REVISED THORNTON CREEK HYDRAULIC REPORT

INTRODUCTION

In response to your review comments dated December 5, 1990, the following changes have been made to all relevant hydraulic backwater computer models:

NORMAL BRIDGE METHOD:

Both bridges modeled have been modified so that the normal bridge method is used for LOW-FLOW situations. The special bridge variables XK and BWP were both changed from non zero values to zeros so that an accurate bridge loss could be computed.

DIVIDED FLOW ANALYSIS:

The split flow option used to portray the South-West diversion of flow along the railroad tracks was modified so that the energy grade lines for both the split flow model (SPL290.O) and the overland flow model (OVERL.O) were equal. Several iterations were used to determine what slope used in the split flow model would reveal the proper energy grade line. A slope of .004 in the existing SPL290.O model revealed an EGL of 830.00 at section 700. The overland flow model OVERL.O calculated an EGL of 830.00 at section 1730 and hence .004 is used to accurately model the correct existing split flow of 137.74 cubic feet per second.

A proposed split flow was also determined from the model PR290BS.O which includes the proposed bridge and fill. This models starting water surface elevation is taken as 827.04 as opposed to 827.11 for all existing models because of the reduction in BFE at cross section 7635 of the rouge river due to the removal of the 22' Old Novi Road Bridge. We have received a permit from the County to remove this bridge. A slope of .004 in the proposed split flow also reveals consistent energy grade lines.

PROPERTY OWNERSHIP

Fill is proposed on the South side of Thornton Creek in the proximity of sections 332 and 532. Since property is owned by the client on the opposite side of this proposed fill, equal encroachment criteria will not be required here.

Fill was originally proposed in the vicinity of section 8065 on the Rouge River, however, due to wetlands concerns, and local D.N.R. recommendations, we have decided to move the road to the West side of the existing sanitary sewer holding tank. This relocation allows us to entirely eliminate the crossing of wetlands in this area and also eliminates the need for fill in the floodplain at cross sections 8065, 8135, and 8283. However, cross section 7835 still requires minimum fill in the floodplain which will be addressed in the Rouge River analysis under separate cover.

DIVIDED FLOW

Between cross sections 850 and 1250 a series of divided flow messages have been eliminated by adding necessary encroachment information. At XSEC 850 a left bank encroachment was added to reflect the required 1 on 4 expansion of flow through the existing railroad bridge. A right bank encroachment was added to eliminate ineffective flow areas to the right and below the top of the berm in that area. At XSEC 1070 ineffective flow areas to the right and below the berm elevation were also eliminated with encroachment data. XSEC 1250 was modified with both left and right encroachment data to portray the actual conveyance characteristics.

Also, encroachment data was added to correctly model the conveyance of flow within the existing concrete channel. Now all flow is contained within the main channel as it should be.

REVISED RESULTS

SPL340.O

This model consists of existing topography and represents existing conditions with the 1987 restudy 100 year flow rate of 340 cfs. The normal depth split flow option was used to determine how much flow was actually diverting parallel to the railroad tracks to the South-West **before** the Lexington Green Detention Basin is constructed. The split flow calculated is 169.0 cfs, therefore, 171.0 cfs is conveyed through the railroad tracks. Encroachments were made at cross sections 332, 532, 700, and 850 to reflect flow contracting at about a 1 to 1 ratio and expanding at about a 4 to 1 ratio. Also, encroachments were made at sections 850, 1070, and 1250 to eliminate ineffective flow areas to the right and below the right overbank berm elevation. This model represents true **EXISTING CONDITIONS** before completion of the Lexington Green Detention Basin.

SPL290.O

This computer model is identical to the above model except that the 100 year flow rate is calculated with the addition of the Lexington Green Detention Basin and the minor routing methodology changes as described in the hydrology section of the original report. This basin is currently working and will be complete when final erosion prevention measures have been placed. The flow rate resulting from this basin is 290 cfs and the split flow calculated with this flow rate is 137.74 cfs. Therefore, 152.26 cfs is conveyed through the existing railroad tracks. This model represents the effect the addition of the Lexington Green Detention basin has on base flood elevations along with the effects on BFE's due to hydrologic routing methodology changes.

PR290BS.O

This model includes the proposed flow rate of 290 cfs, the bridge, the road, filling, and the proposed split flow along the Railroad tracks. The model, therefore, represents the true PROPOSED CONDITIONS and includes hydrologic changes due to detention and routing methodology changes, along with hydraulic modifications due to a proposed structure and filling. The split flow calculated from this model is 132.02 cfs, hence 157.98 cfs is conveyed through the railroad tracks and the proposed Thornton Creek bridge. Encroachments have been included to portray actual conveyance characteristics.

OVERE.O

This model is for the existing diversion of flow along the railroad tracks. The 137.74 cfs which was calculated from the existing split flow model (SPL290.O) was used to determine the existing 100 year flood boundary for the overland flow portion of Thornton Creek. This areas flood boundary can be seen on site plan #1.

OVERP.O

This model is for the proposed diversion of flow along the railroad tracks. The 132.02 cfs which was calculated from the proposed split flow model (PR290BS.O) was used to determine the proposed 100 year flood boundary for the overland flow portion of Thornton Creek. This areas flood boundary can be seen on site plan #1 also. This reduction in overland flow is a direct consequence of the reduction in starting water surface elevation for the proposed condition due to the lowering of the 100 year base flood elevation at section 7635 from 827.11 to 827.04.

CONCLUSIONS

The two models that illustrate best the impact that the proposed project has on Base Flood Elevations are SPL290.O (existing topography) and PRO290BS.O (proposed). The proposed model was altered to include the proposed road, fill, and bridge. Table A below compares the two models and their respective BFE's.

STATION (#)	SPL290.O (FT.)	PR290BS.O (FT.)	EASEMENT NEEDED (FT.)
122	827.11	827.04	NONE
332	826.99	826.61	NONE
397	N/A	827.85	NONE
457	N/A	828.23	NONE

2140	835.50	835.50	NONE

TABLE A: PROPOSED (SPL290.0) VS PROPOSED (PR290BR.O) ELEVATIONS

Clearly, a rise in the 100 year base flood elevation occurs at section 532 which is directly upstream of the proposed bridge.

If however, we compare Existing and Proposed conditions or SPL340.O verses PR290BS.O taking into consideration the 100 year flow reduction due to the Lexington Green Detention Basin, then the observed reductions in BFE's are greater then before, see table B below. Also, the increase due to fill at cross section 532 is .14' less when this comparison is used.

STATION (#)	SPL340.O (FT.)	PR290BS.O (FT.)	EASEMENT NEEDED (FT.)
122	827.11	827.04	NONE
332	826.93	826.61	NONE

1520	833.22	832.99	NONE
1790	834.83	834.58	NONE
2140	835.75	835.50	NONE

TABLE B: EXISTING (SPL340.0) VS PROPOSED (PR290BR.O) ELEVATIONS

Clearly, a rise in base flood elevation occurs at section 532 which is directly upstream of the proposed bridge. This increase, however, is confined within the boundaries of the owners property line and hence does not effect other property owners in the area.

Since an increase in 100 year base flood elevation is unavoidable due to the proposed construction, and since the City of Novi's floodplain ordinance number 77-80 section 5.02-d.(1) allows no such an increase, we are currently revising the ordinance to be consistent with the State's floodplain regulation guidelines, which allow for floodplain and storm water management practices.

ELEVATION REFERENCE MARKS

REFERENCE MARK	ELEVATION (FEET NGVD)	DESCRIPTION OF LOCATION
RM1	836.80	Chiseled cross on top of southwest abutment of CSX railroad bridge over Thornton Creek.
RM2	830.37	Top east end of cross culvert under Ennisfore Drive at northeast corner of intersection with Nine Mile Road.
RM3	830.22	Chiseled cross on centerline of west end of northwest wingwall of Meadowbrook Road bridge over Ingersol Creek.
RM4	846.69	Chiseled square cut in top of sidewalk at northwest corner of Willowbrook Drive bridge over Ingersol Creek.
RM5	853.32	Railroad spike on south side of power pole located about 50 feet northwest of box culvert for Ingersol Creek under Ten Mile Road.
RM6	852.64	Chiseled station "88 + 42" on centerline of north headwall of culvert for Ingersol Creek under Grand River Avenue.
RM7	860.65	Cross on north bolt of fire hydrant flange located at southeast corner of intersection of Lebost Drive and Ten Mile Road.
RM8	862.00	Chiseled square cut on north end of east abutment of CSX railroad bridge over Walled Lake Branch.
RM9	875.23	Railroad spike on south side of powerpole located at northwest corner of Ten Mile Road and CSX railroad crossing.
RM10	887.01	Top of east end of 42-inch corrugated metal culvert for Chapman Creek under Novi Road.
RM11	849.87	Railroad spike on northwest side of powerpole located at southeast corner of intersection of Nine Mile Road and Novi Road.
RM12	874.12	Railroad spike in northwest side of powerpole located at southwest corner of intersection of Nine Mile Road and Center Street.

LEGEND

SPECIAL FLOOD HAZARD AREAS INUNDATED BY 100-YEAR FLOOD

- ZONE A — No base flood elevations determined.
- ZONE AE — Base flood elevations determined.
- ZONE AH — Flood depths of 1 to 3 feet (usually areas of ponding); base flood elevations determined.
- ZONE AO — Flood depths of 1 to 3 feet (usually sheet flow on sloping terrain); average depths determined; for areas of alluvial fan flooding, velocities also determined.
- ZONE A99 — To be protected from 100-year flood by Federal flood protection system under construction; no base elevations determined.
- ZONE V — Coastal flood with velocity hazard (wave action); no base flood elevations determined.
- ZONE VE — Coastal flood with velocity hazard (wave action); base flood elevations determined.

FLOODWAY AREAS IN ZONE AE

OTHER FLOOD AREAS

- ZONE X — Areas of 500-year flood; areas of 100-year flood with average depths of less than 1 foot or with drainage areas less than 1 square mile; and areas protected by levees from 100-year flood.

OTHER AREAS

- ZONE X — Areas determined to be outside 500-year flood plain
- ZONE D — Areas in which flood hazards are undetermined.

UNDEVELOPED COASTAL BARRIERS

Flood Boundary
Floodway Boundary
Zone D Boundary
Boundary Dividing Special Flood Hazard Zones, and Boundary Dividing Areas of Different Coastal Base Flood Elevations Within Special Flood Hazard Zone.

NOTES

This map is for use in administering the National Flood Insurance Program; it does not necessarily identify all flammable areas outside the Special Flood Hazard Area or all areas subject to flooding, particularly from local drainage sources of small size.

Areas of Special Flood Hazard (100-year flood) include zones, A, AE, A1-A30, AH, AO, AVE, V, VE and V1-V30.

Certain areas not in Special Flood Hazard Areas may be protected by flood control structures.

Boundaries of the floodways were computed at cross-sections and interpolated between cross-sections. The floodways were based on hydraulic considerations with regard to requirements of the Federal Emergency Management Agency.

Floodway widths in some areas may be too narrow to show to scale. Refer to Floodway Data Table where floodway width is shown at 500 inch.

Coastal base flood elevations apply only landward of the shoreline.

This map incorporates approximate boundaries of coastal barriers established under the Coastal Barrier Resources Act (PL 97-348).

Corporate limits shown are current as of the date of this map. The user should contact appropriate community officials to determine if corporate limits have changed subsequent to the issuance of this map.

For adjoining panels, see separately printed Map Index.

Re: Flood Insurance Study - City of Novi
Bishop Creek Hydraulic Investigation

Ref: J&A File No. 5555-46-1

Gentlemen:

Enclosed you will find the necessary information for a review of the Bishop Creek in the City of Novi. The data provided is the same as on the March 3, 1976, and April 14, 1976, submittals except the culvert methodology has been revised according to our meeting of May 21, 1976, and subsequent phone calls.

We would appreciate a review and approval of this study by August 4, 1976. If you have any questions, please call me.

Thank you for your cooperation.

Sincerely,

William C Rossow

HYDRAULIC ANALYSIS

Introduction

The stream that was studied is the Bishop Creek, in the City of Novi, Oakland County, Michigan. The study begins at the confluence of the Bishop Creek with the Patnales Drain and continues for approximately 2.4 river miles until Interstate 96. The discharges were computed by the unit hydrograph-infiltration capacity method developed by Dr. Ernest F. Brater. The 10-, 50-, 100- and 500-year flood frequency flows used in this study have been approved by the Michigan Department of Natural Resources.

Method of Analysis

The flood profiles were computed by the HEC-2 computer program developed by the U.S. Army Corps of Engineers.[1]

All bridges have been modeled for the requirements of the HEC-2 normal bridge routine, except encroachment method 1 was used in lieu of levees. The bridges were checked, by manual calculations, for the occurrence of pressure flow (inlet or outlet control) and/or weir flow. The tail-water elevations used in conjunction with outlet control were determined by comparing encroached and unencroached valley sections one foot down-stream of the bridges. With the aid of photographs and field trips at the site of the bridges, a judgment was made as to the likelihood of

the downstream section being either a pool with a small velocity (unencroached section) or an expanding section with a high velocity producing an adverse scope (encroached section). If pressure flow and/or weir flow occur, the HEC-2 normal bridge routine was not used and the manually calculated water surface was inputted by use of the "X5" card. (Exception: if the weir is under high submergence, then HEC-2 normal bridge routine was used.[2]) When the "X5" card is used, the HEC-2 hydraulic calculations for the bridge are ignored as these calculations are no longer valid. If pressure and/or weir flow occurs at a bridge, then the upstream encroachments were removed to reflect the presence of a backwater pool.

Weir stage-discharge information was calculated by the computer using the standard equation, $Q = CLH^{3/2}$. The weir is divided along its length into one-foot segments. After being calculated through each setment, flows are summed.

Variables and Coefficients

The roughness factors (Manning's "n") were established by comparing the photographs and descriptions by Chow[3] with photographs and field inspection trips taken in the City of Novi.

There is currently no rational method of evaluating coefficients or contraction and expansion.[4] The coefficients of contraction and expansion used in this study were, respectively, 0.3 and 0.5, as suggested by the example sketched in Exhibit 5 in the HEC-2 Users Manual.[5]

The orifice discharge coefficients for outlet control used in this study were taken from charts published by the Bureau of Public Roads.[6] These coefficients represent the losses due to inlet, outlet and friction. For inlet control, nomographs from the Bureau of Public Roads[7] were used. The weir discharge and submergence coefficients were taken from charts supplied by the Michigan Department of Natural Resources.

Starting Point

The profile computation for Bishop Creek began at the confluence with the Patnales Drain. Starting elevations were taken from the Patnales Drain Study by using the water elevation calculated at the confluence with Bishop Creek for each frequency flood studied.

1) COUNTY: OAKLAND

2) STUDY NAME: NOVI TOWNSHIP

3) WATERCOURSE: PATNALES DRAIN

4) DOCUMENT TYPE: HYDRAULIC ANALYSIS

HYDRAULIC ANALYSIS

Introduction

The stream being investigated is the Patnales Drain in the City of Novi, Oakland County, Michigan. The study limits are from the C & O Railraod Bridge upstream of Northville's Mill Pond to the southbound exit ramp from Interstate 96 to Interstate 275, a distance of approximately 4.6 river miles. The discharges were computed by the unit hydrograph-infiltration capacity method developed by Dr. Ernest F. Brater. The 10-, 50-, 100- and 500-year flood frequency flows used in this study have been approved by the Michigan Department of Natural Resources.

Method of Analysis

All constrictions (culverts and bridges) in this study have been modeled for low flow conditions according to the requirements of the normal bridge routine of HEC-2. They were then analyzed, after removing the encroachments, by hand calculations for pressure flow (inlet or outlet control) and weir flow or a combination of flows. The correct water surface elevations, if different from those calculated by the normal bridge routine, were then entered into the backwater computations on the upstream side of the constriction by the use of an X-5 card in the HEC-2 program. The two sections that describe the geometry of the bridge were left in place for informational purposes. When an X-5 card is used, the HEC-2 hydraulics for these two sections is ignored.

Because of the requirements of the HEC-2 normal bridge routine, the original field-surveyed cross sections that were taken within two hundred feet downstream of all constrictions have been physically relocated to points that are one foot from the upstream and downstream faces of the constrictions.

In order to more efficiently model the floodway for the contractions and expansions caused by these constrictions, these same sections were placed upstream and downstream of the constrictions at locations that represent the full cross section unaffected by the constriction, as set forth in Exhibit 4 of the HEC-2 Users Manual for the required cross sections using the normal bridge routine.

The guidelines set forth on pages 18 through 21, inclusive, in the Applications of HEC-2 Bridge Routines, The Hydrologic Engineering Center, Training Document No. 6, were used to determine the location of these cross sections. Accordingly, the downstream section was placed at about four (4) times the average length of the side constriction caused by the bridge or culvert abutments. The upstream section was placed a distance equal to the bridge or culvert contraction. These distances have been modified in some cases due to the physical encroachments of buildings, high banks, etc. The coefficients of contraction and expansion used in Exhibit 5 in the HEC-2 Users Manual are 0.3 and 0.5, respectively. These values were used in this study since the example situation in the Users Manual closely approximates typical conditions found on the Patnales Drain.

Variables and Coefficients

The roughness factors (Manning's "n") were established by comparing the photographs and descriptions found on pages 101 to 123 in Open-Channel Hydraulics by Ven Te Chow, with photographs and field inspection trips taken in the City of Novi. In general the following values were used:

Description	Manning "n"
Channel Bottoms	
1. Earth, winding and sluggish with grass and some weeds	.03
2. Streams on plain, clean bottom, some pools and shoals	.04
3. Channels not maintained, uncut weeds and brush on sides, clean bottom	.05
Flood Plains	
1. Short grass, no brush	.03
2. Light to medium brush and trees in summer	.07
3. Medium to dense brush in summer	.10

The contraction and expansion coefficients used in the Novi Study were .3 and .5, respectively. Generally, the changes in shape of the stream cross sections were not considered gradual transitions; they more nearly approached the transition section of bridges and culverts. Although this assumption may lead to a higher eddy loss than actually occurs, it should have little effect on profile computations. As stated by Beasley in A Pilot Study Stream-flow Simulation and Flood Profile Determination in Ohio on page 143, ". . . a

sensitivity study . . . has indicated that the HEC-2 is not very sensitive to these [contraction and expansion] coefficients and little time should be spent on their selection."

The orifice discharge coefficients for outlet control used in this study were taken from the Hydraulic Charts for the Selection of Highway Culverts, Hydraulic Engineering Circular No. 5, Bureau of Public Roads. These coefficients represent the addition of the inlet loss, outlet loss and loss due to friction. For inlet control, nomographs from Circular No. 5 (above) were used. If nomographs did not exist for a particular culvert, and the entrance was submerged, then the equation found on page 209 of Design of Small Channel Structures, U.S. Department of Interior, Bureau of Reclamation, was used. This same equation is found on page 288 of Applied Hydraulics in Engineering by Morris and Wiggert. If the entrance was unsubmerged, then either the weir principle was applied or the culvert was made equivalent to a round pipe and solved by the equations found on pages 115 and 116 of Handbook of Concrete Pipe Hydraulics, Portland Cement Association.

The weir discharge coefficients were taken from charts supplied by the Michigan Department of Natural Resources. These coefficients were inserted into a computer program that divides the weir into one-foot segments and computes the flow through each segment by the standard weir formula, $Q = CLH^{3/2}$. For a given upstream water surface elevation, the summation of these segments equals the total flow over the weir. If the weir was submerged, a submergence factor (also supplied by the Michigan DNR) for either a gravel or hard surface was manually applied.

Starting Point

The profile computation began at a point forty feet downstream of the C & O Railroad Bridge, upstream of Northville's Mill Pond. The starting elevations were extrapolated from a rating curve plotted from the information found on page A-95 of Technical Appendix Draft FPI-Middle River Rouge - Northville & Vicinity by the Corps of Engineers, Detroit District, 1970.

Re: Flood Insurance Study - City of Novi
Walled Lake Branch of the Middle River Rouge
Tributary "A" and Tributary "B"

Ref: J&A File No. 5555-46-1

Gentlemen:

Enclosed you will find the necessary information for a review of the above referenced streams in the City of Novi. The data provided is the same as on March 3, 1976, and April 14, 1976, submittals except the culvert methodology has been revised according to our meeting of May 21, 1976, and subsequent phone calls.

We would appreciate a review and approval of this study by September 10, 1976. If you have any questions, please call me.

Thank you for your cooperation.

Sincerely,

William C Rossow

HYDRAULIC ANALYSIS

Introduction

The stream that was studied is the Walled Lake Branch of the Middle River Rouge, in the City of Novi, Oakland County, Michigan. The study begins at Meadowbrook Lake, continues for approximately 5.8 river miles until 750' southwest of Walled Lake. Included in this study are two unnamed tributaries, referred to as Tributary "A" and Tributary "B." The study of Tributary "A" begins at its confluence with the Walled Lake Branch, south of Ten Mile Road, continues for approximately 1.0 river mile until Ten Mile Road. The study of Tributary "B" begins at its confluence with the Walled Lake Branch, east of Novi Road, continues for approximately 1.3 river miles, until Taft Road.

The discharges are computed by the unit hydrograph-infiltration capacity method developed by Dr. Ernest F. Brater. The 10-, 50-, 100- and 500-year flood frequency flows used in this study have been approved by the Michigan Department of Natural Resources (letter dated November 5, 1975.)

Method of Analysis

The flood profiles were computed by the HEC-2 computer program developed by the U.S. Army Corps of Engineers.[1]

All bridges have been modeled for the requirements of the HEC-2 normal bridge routine. The bridges were checked, by manual calculations, for the occurrence of pressure flow (inlet or outlet control) and/or weir flow. The tailwater elevations used in conjunction with outlet control were determined by

comparing encroached and unencroached valley sections one foot downstream of the bridges. With the aid of photographs and field trips at the site of the bridges, a judgment was made as to the likelihood of the downstream section being either a pool with a small velocity (unencroached section) or an expanding section with a high velocity producing an adverse scope (encroached section). If pressure flow and/or weir flow occur, the HEC-2 normal bridge routine was not used and the manually calculated water surface was inputted by use of the "X5" card. (Exception: if the weir is under high submergence, then HEC-2 normal bridge routine was used.[2]) When the "X5" card is used, the HEC-2 hydraulic calculations for the bridge are ignored as these calculations are no longer valid. If pressure and/or weir flow occurs at a bridge, then the upstream encroachments were removed to reflect the presence of a backwater pool.

Weir stage-discharge information was calculated by the computer using the standard equation, $Q = CLH^{3/2}$. The weir is divided along its length into one-foot segments. After being calculated through each segment, flows are summed.

Variables and Coefficients

The roughness factors (Manning's "n") were established by comparing the photographs and descriptions by Chow[3] with photographs and field inspection trips taken in the City of Novi.

The orifice discharge coefficients for outlet control used in this study were taken from charts published by the Bureau of Public Roads.[4] These

coefficients represent the losses due to inlet, outlet and friction. For inlet control, nomographs from the Bureau of Public Roads[5] were used. If nomographs did not exist for a particular bridge, then the equation $\left|\frac{V^2}{2g} + \frac{1}{C^2}\right| + \frac{D}{2} = HW$ [6, 7] was used if the entrance was submerged. If the entrance was unsubmerged, then either the weir principle was applied or the culvert was made equivalent to a round pipe[8] to be solved. The weir discharge and submergence coefficients were taken from charts supplied by the Michigan Department of Natural Resources.

Starting Point

The profile computation for the Walled Lake Branch began at Meadowbrook Lake, which is regulated by a dam at its southern end. A stage-discharge relationship was calculated to determine the water elevation for each frequency flood passing over this ~~control point~~.

The profile computation for Tributary "A" and Tributary "B" began at their respective confluence with the Walled Lake Branch. By computing the water elevation on the Walled Lake Branch at these confluences for each frequency flood studied, the starting elevations were determined.

Discussion

A condition of divergence of flow exists on the Walled Lake Branch when the discharge is of flood magnitude. This division begins upstream of section AP and continues to its confluence downstream of section AA. The cause of this division of flow can be traced to the inadequate capacity

of the stream enclosure under the property of the Paragon Steel Plant. This enclosure consists of two 4.5' diameter RCP and one 2.0' diameter RCP which are 390' long. It is apparent that as the discharge increases, the backed up water will seek another flow route.

This condition was analyzed using the procedure recommended by Chow.[9]

3) WATERCOURSE: NOVI-LYON DRAIN

4) DOCUMENT TYPE: HYDRAULIC ANALYSIS

00BREAK00

HYDRAULIC ANALYSIS

Introduction

The stream being investigated is the Novi-Lyon Drain in the City of Novi, Oakland County, Michigan. The study starts from the Johns Road Culvert, about 1000 feet north of Eleven Mile Road, to the Nine Mile Road Culvert, 20 feet east of Garfield Road, covering a distance of approximately 2.9 river miles. Included in this study is one unnamed tributary referred to as Tributary "C." The study of Tributary "C" begins at its confluence with Novi-Lyon Drain, downstream of Farmfield Crossing Bridge No. 5281, and continues for 1.9 river miles until Beck Road. By combining Brater's unit hydrograph-infiltration capacity method with the TR-20 computer program, the 10-, 50-, 100-, and 500-year flood frequency flows were calculated. A significant storage effect that occurred between Ten Mile Road and Nine Mile Road has been taken into consideration.

Method of Analysis

The water surface profiles of all constrictions (culverts and bridges) in this study have been determined by hand calculations, except for those reflecting low flow conditions and completely submerged conditions which can be considered as the backwater profiles. The results of these hand calculations were then entered into the backwater computations on the upstream side of the constriction by the use of an X-5 card in the HEC-2 program. The HEC-2 hydraulics for the two sections that describe the

geometry of the constriction is ignored and replaced by the most representative section, which is moved to points 1.0 foot off the upstream and downstream faces of the constriction. In order to more efficiently model the floodway for the contractions and expansions caused by these constrictions, these same sections were placed upstream and downstream of the constrictions at locations which represent the full cross section unaffected by the constriction.[1] As suggested by the Hydrologic Engineering Center,[2] the downstream section was placed at about four times the average length of the side constriction caused by the bridge or culvert abutments and the upstream section was placed at a distance roughly equal to the bridge or culvert contraction.

There is currently no rational method of evaluating coefficients of contraction and expansion.[3] The coefficients of contractions and expansions used in this study were, respectively, 0.3 and 0.5, as suggested by the example sketched in Exhibit 5 of the HEC-2 Users Manual.

The limits of computational accuracy using the above method of analysis for constrictions will generate a water surface profile with an accuracy of $\pm$ 0.5 foot.

[2] Applications of HEC-2 Bridge Routines, The Hydrologic Engineering Center, Training Document No. 6.

[3] Chow, V. T., Open Channel Hydraulics, McGraw-Hill, 1959, P. 267.

The discharges were computed by Brater's unit hydrograph-infiltration capacity method and the TR-20 computer program. The former method determines the inflow hydrographs under the conclusion that the unit hydrographs can be correlated with watershed areas and population densities. The latter one determines outflow hydrograph by using "storage-indication method" for both channel and reservoir routing.

Variables and Coefficients

The roughness factors (Manning's "n") were established by comparison of photographs and descriptions found on pages 101 to 123, in Open Channel Hydraulics, by V. T. Chow, with photographs and field inspection trips taken in the City of Novi.

The contraction and expansion coefficients used herein were 0.3 and 0.5, respectively. It is found that these coefficients only have little effect on profile computation.[4]

The orifice discharge coefficients for outlet control used in this study were taken from the Hydraulic Charts for the Selection of Highway Culverts, Hydraulic Engineering Circular No. 5, Bureau of Public Roads. These coefficients represent the addition of the inlet loss, outlet loss and loss due to friction. For inlet control, nomographs from Circular No. 5 (above) were used. If nomographs did not exist for a particular culvert, and the

---

[4]Beasley, J. G., A Pilot Study Streamflow Simulation and Flood Profile Determination in Ohio, the Ohio State University, Columbus, Ohio, Nov. 1974.

entrance was submerged, then the equation found on page 209 of Design of Small Channel Structures, U.S. Department of Interior, Bureau of Reclamation, was used. This same equation is found on page 288 of Applied Hydraulics in Engineering by Morris and Wiggert. If the entrance was unsubmerged, either the weir principle was applied or the culvert was made equivalent to a round pipe and solved by the equations found on pages 115 and 116 of Handbook of Concrete Pipe Hydraulics, Portland Cement Association.

The weir discharge coefficients were taken from charts supplied by the Michigan Department of Natural Resources. These coefficients were inserted into a computer program that divides the weir into one foot segments and computes the flow through each segment by the standard weir formula, $Q = C L H^{3/2}$. For a given upstream water surface elevation, the summation of these segments equals the total flow over the weir. If the weir is submerged, a submergence factor (also supplied by the Michigan DNR) for either a gravel or hard surface is manually applied.

Starting Point

The calculations began at the Johns Road Culvert about 1.2 miles downstream from the city limit of Novi. This starting point is selected to ensure that the water elevations at the city limit of Novi are correct, since 1.2 miles is far enough to eliminate the small error of the selected starting water elevations that probably occurred at the Johns Road Culvert. Three different starting elevations have been selected for the water elevation profile calculation. The results show that these three profiles overlap at the section that

is about 0.5 mile upstream of the starting point. The approximate starting water elevations at Johns Road culvert were determined by slope-area method. The calculated water surface elevations at the section where Tributary "C" comes to join Novi-Lyon Drain were used as the starting water elevations for the study of Tributary "C."

Discussion

The large area between Ten Mile Road and Nine Mile Road is very flat and the elevation of this area is about 5.0 feet lower than the surface elevation of Ten Mile Road. Unfortunately, the Ten Mile Road culvert is a CMP pipe with a diameter of 4 feet which is not large enough to discharge the inflows. These observations imply that a significant storage effect between Ten Mile Road and Nine Mile Road must be taken into account. Therefore, this study was divided into two parts at Ten Mile Road (1) a riverine study downstream calculated by HEC-2, and (2) pool elevations upstream calculated by TR-20. Since the stage-discharge relationship of this culvert depends on the tail-water elevations, a number of trials were made to determine flow through the culvert for various headwater elevations. The stage-discharge-storage relationship was put into the TR-20 program to calculate the upstream water surface elevations and discharges for each frequency flood at this "temporary lake."

HYDRAULIC ANALYSIS

Introduction

The stream being investigated is the Thornton Creek in the City of Novi, Oakland County, Michigan. The study limits are from its confluence with the Patnales Drain, south of Nine Mile Road, to Ten Mile Road west of Taft Road, a distance of approximately 3.5 river miles. Included in the scope of study is a small segment of overland flow which occurs just upstream of the confluence.

The discharges were computed by the unit hydrograph-infiltration capacity method developed by Dr. Ernest F. Brater. The 10-, 50-, 100-, and 500-year flood frequency flows used in this study have been approved by the Michigan Department of Natural Resources.

Method of Analysis

All constrictions (culverts and bridges) in this study have been modeled for low flow conditions according to the requirements of the normal bridge routine of HEC-2. They were then analyzed by hand calculations for pressure flow (inlet or outlet control) and weir flow or a combination of flows. The tailwater elevations used in conjunction with outlet control were determined by comparing encroached and unencroached valley sections one foot downstream of the constriction. With the aid of photographs and field inspection trips to the site of the constriction, a judgment was made as to the likelihood of the downstream section being either a pool with a small velocity (unencroached

section) or an expanding section with a high velocity producing an adverse slope (encroached section).

If the constriction was flowing under pressure and/or weir flow existed, then the correct water surfaces from the hand calculations were entered into the backwater computations at the full valley section one foot upstream of the constriction by the use of an X-5 card in the HEC-2 program. This full valley section reflects the presence of a pool. When an X-5 card is used, the two sections that describe the geometry of the bridge are left in place for informational purposes and the HEC-2 hydraulics for these two sections is ignored.

Because of the requirements of the HEC-2 normal bridge routine, the original field-surveyed cross sections that were taken within two hundred feet downstream of all constrictions have been physically relocated to points that are one foot from the upstream and downstream faces of the constrictions.

In order to more efficiently model the floodway for the contractions and expansions caused by these constrictions, these same sections were placed upstream and downstream of the constriction at locations that represent the full cross section unaffected by the constriction, as set forth in Exhibit 4 of the HEC-2 Users Manual for the required cross sections using the normal bridge routine. These same cross sections are also required for the special bridge routine as set forth in Exhibit 3 of the HEC-2 Users Manual.

The guidelines set forth on pages 18 through 21, inclusive, in the Applications of HEC-2 Bridge Routines, The Hydrologic Engineering Center, Training Document No. 6, were used to determine the location of these cross sections. Accordingly, the downstream section was placed at about four (4) times the average length of the side constriction caused by the bridge or culvert abutments. The upstream section was placed a distance equal to the bridge or culvert contraction. These distances have been modified in some cases due to the physical encroachments of buildings, high banks, etc.

The coefficients of contraction and expansion used in Exhibit 5 in the HEC-2 Users Manual are 0.3 and 0.5, respectively. These values were used in this study since the example situation in the Users Manual closely approximates typical conditions found on the Thornton Creek.

The limits of computational accuracy using the above method of analysis for constrictions will reflect a water surface profile with an accuracy of $\pm$ .5 foot.

Variables and Coefficients

The roughness factors (Manning's "n") were established by comparing the photographs and descriptions found on pages 101 and 123 in Open-Channel Hydraulics by Ven Te Chow, with photographs and field inspection trips taken in the City of Novi.

The contraction and expansion coefficients used in the Novi Study were .3 and .5, respectively. Generally, the changes in shape of the stream cross

sections were not considered gradual transitions; they more nearly approached the transition section of bridges and culverts. Although this assumption may lead to a higher eddy loss than actually occurs, it should have little effect on profile computations. As stated by Beasley in A Pilot Study Streamflow Simulation and Flood Profile Determination in Ohio on page 143, " . . . a sensitivity study . . . has indicated that the HEC-2 is not very sensitive to these [contraction and expansion] coefficients and little time should be spent on their selection."

The orifice discharge coefficients for outlet control used in this study were taken from the Hydraulic Charts for the Selection of Highway Culverts, Hydraulic Engineering Circular No. 5, Bureau of Public Roads. These coefficients represent the addition of the inlet loss, outlet loss and loss due to friction. For inlet control, nomographs from Circular No. 5 (above) were used. If nomographs did not exist for a particular culvert, and the entrance was submerged, then the equation found on page 209 of Design of Small Channel Structures, U.S. Department of Interior, Bureau of Reclamation, was used. If the entrance was unsubmerged, either the weir principle was applied or the culvert was made equivalent to a round pipe and solved by the equations found on pages 115 and 116 of Handbook of Concrete Pipe Hydraulics, Portland Cement Association.

The weir discharge coefficients were taken from charts supplied by the Michigan Department of Natural Resources. These coefficients were inserted into a computer program that divides the weir into one foot segments and computes the flow through each segment by the standard weir formula, $Q = CLH^{3/2}$. For a given

upstream water surface elevation, the summation of these segments equals the total flow over the weir. If the weir was submerged, a submergence factor (also supplied by the Michigan DNR) for either a gravel or hard surface was manually applied.

Starting Point

The profile computations for the Thornton Creek began at its confluence with the Patnales Drain and the starting elevations were taken from the Patnales Drain study. The starting elevations for the overland flow leg were taken at its confluence with the Patnales Drain. Since this was a free outfall situation, the starting elevations were obtained by a weir analysis.

Discussion

The only unusual condition in this study was the overland diversion of flow caused by the earth embankment of the C&O Railroad. The division of flow was determined by the technique illustrated on page 320 and 321 of Open-Channel Hydraulics by Ven Te Chow.

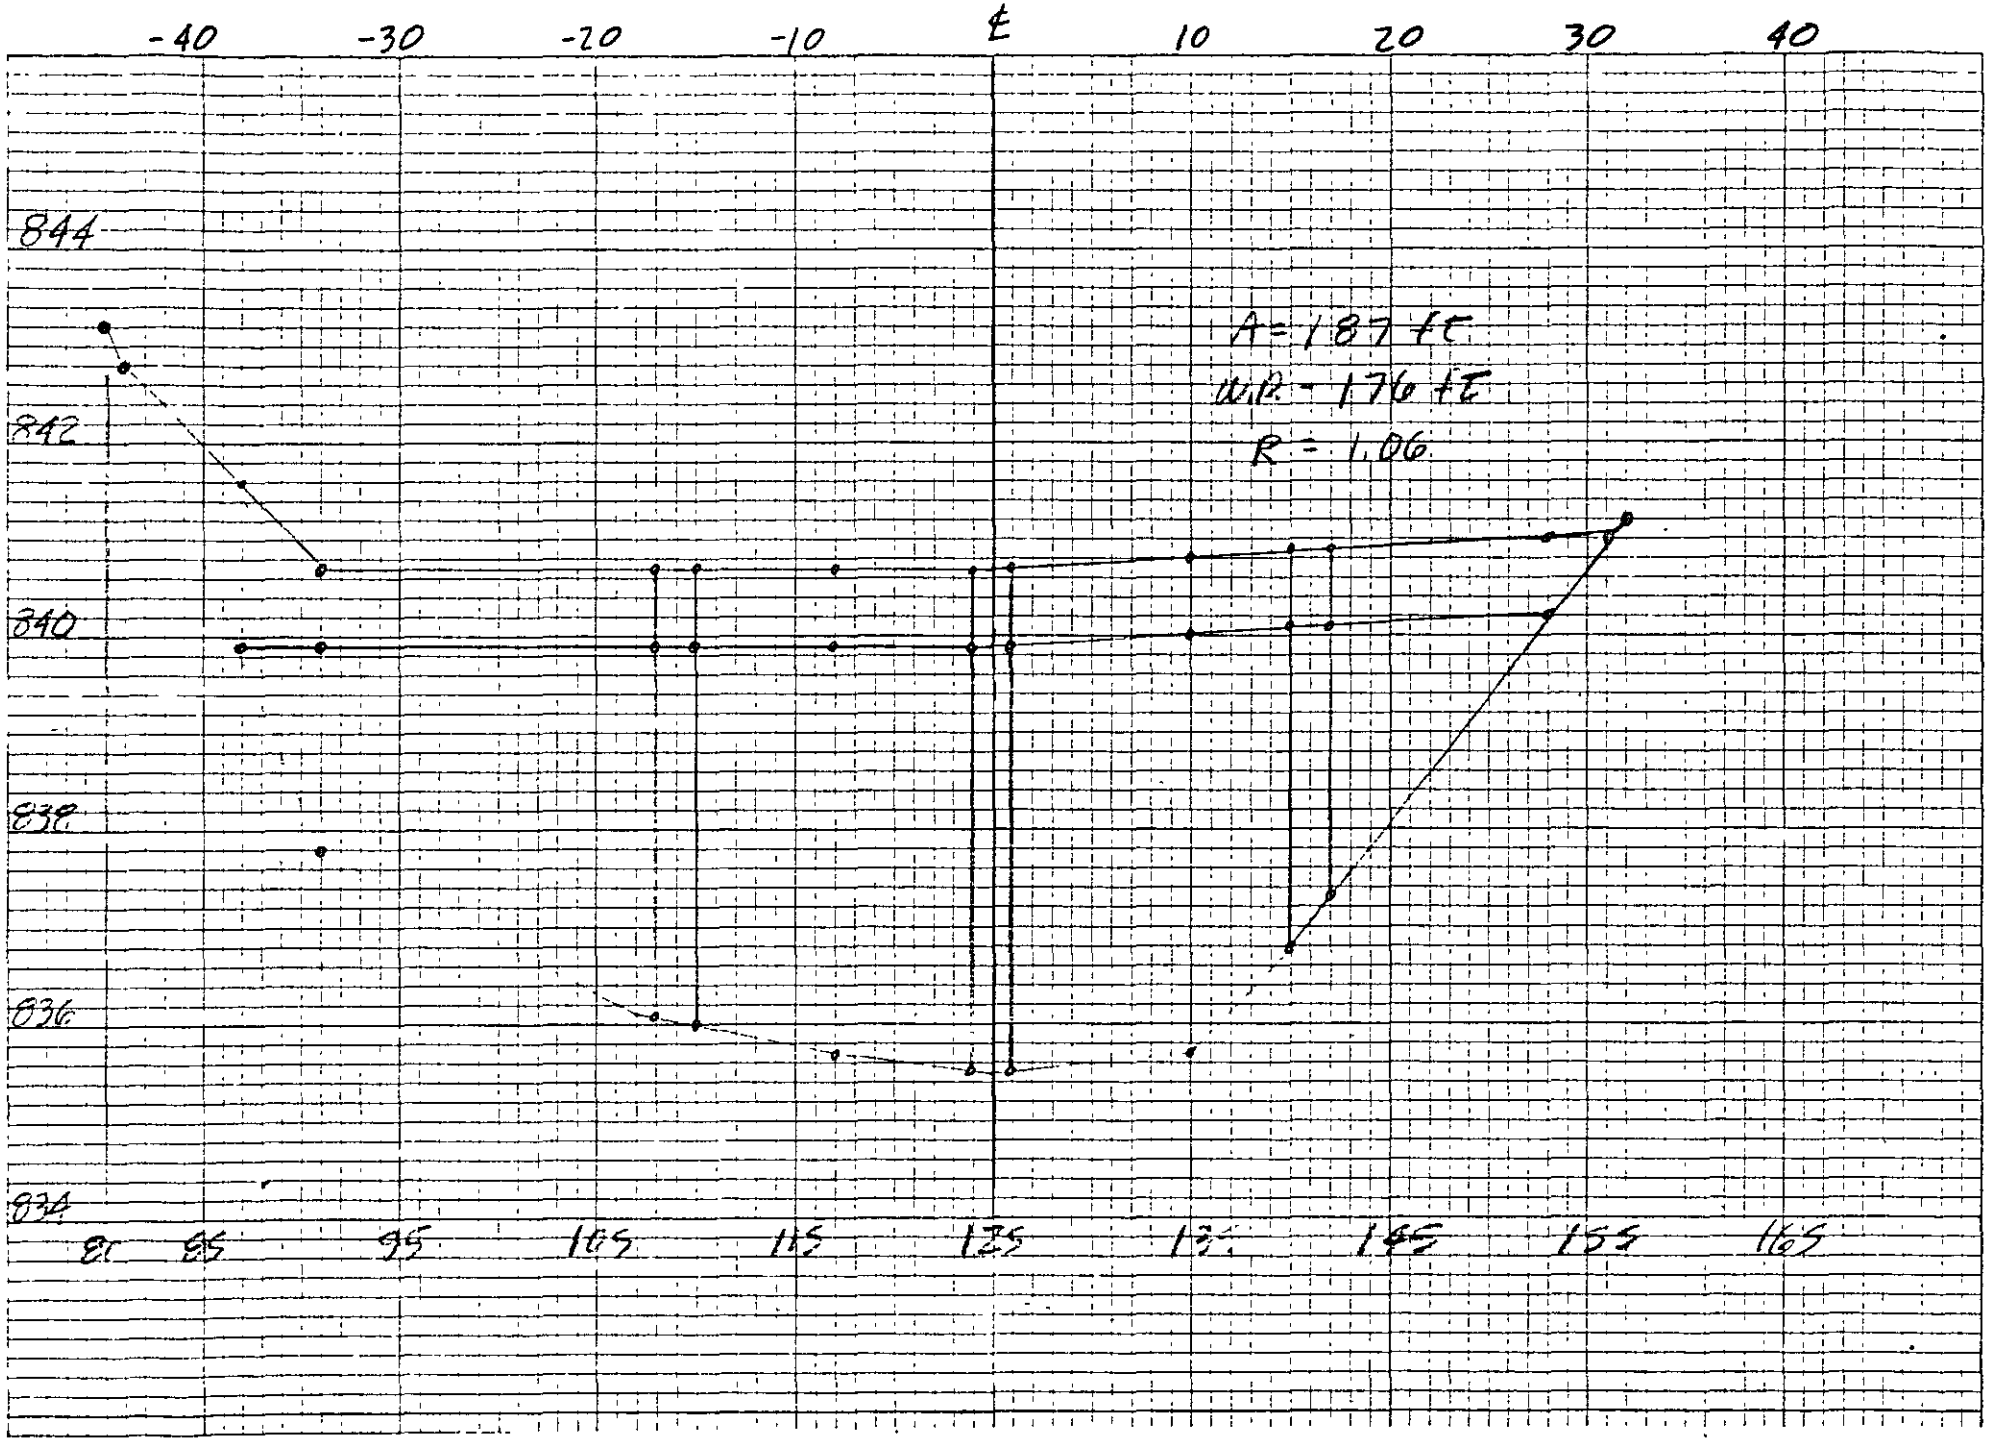
Calculations & Comments

Inlet Control

$HW = \left(\frac{V^2}{2g} \times \frac{1}{C^2}\right) + \frac{D}{2}$ $C = .6$

Outlet Control



$H = .0258\,V^2$

40.7 − 35.5 = 5.20 WEIR FLOW BEGINS

Bridge & abutments are a small obstruction to the flow. Friction losses are the predominate consideration. ∴ Use normal bridge routine.

465				6.77 D					6.62	6.22	897.82	

Calculations & Comments

Inlet Control

$HW = \left(\frac{V^2}{2g} \times \frac{1}{C^2}\right) + \frac{D}{2}$

Outlet Control

$H = .0253\,V^2$

* 97.2 − 91.6 = 5.60 Weir Flow Begins

** Since minimum specific energy occurs within the bridge for all flows HEC-2 output is not valid. ie. supercritical flow.

Correct

Job Name: Novi, FIS | Job No. 5555 | 46 | 1 | 01

Watercourse: Thornton Creek | Weir Location: Taft Road So. of 9 Mile

Weir Description: Gravel | By WCR | Date 12-20-75

1 Q_T	2 HW Elev	3 TW Elev	4 Hc (2-3)	5 $Q_c = A\sqrt{\frac{2gH_c}{1+Ke-\frac{29n^2L}{R^{4/3}}}}$	6 L	7 Avg Rd. El.	8 (6×7)	9 Hw (2-7)	10 C	11 $Q_w = CLH_w^{3/2}$	12 Min. Rd. El.	13 $\frac{D}{H}$ $\left(\frac{3-12}{2-12}\right)$	14 Cs/Cf	15 (11×14)	16 (5+15)

330	897.49		5.89	285						46					331
465	897.82			298						170					468

Calculations & Comments

$Q_c = 201\, H_c^{1/2}$ (Outlet Control)

$HW = \left[\frac{V^2}{2g} \times \frac{1}{C^2}\right] + \frac{D}{2}$ (Inlet Control)

4-8-16

Thornton Creek WCR

Taft Road South of Nine Mile

Half Round Concrete Arch with no wingwalls

10 year flow

$Q = 189$ cfs

$A = 32$ ft^2

$D = 4.95$ ft

Solution as an equivalent round pipe

Equivalent $\phi = 6.38$

Discharge factor $= Q \div D^{5/2} = 1.84$

$$\frac{He}{D} = K \left(1.273 \frac{Q}{D^{5/2}} \right)^m$$

For square edge with headwall $K = .0098$, $m = 2.0$

$$\frac{He}{D} = .0098 \left(1.273 \times 1.84 \right)^2 = .0538 < .105$$

$$\frac{H}{D} + .5 S_o = \frac{Hc}{D} + \frac{He}{D}$$

$$\frac{HW}{4.95} + .5 \times .022 = \frac{4.16}{4.95} + .054$$

$HW = 4.37$ ft

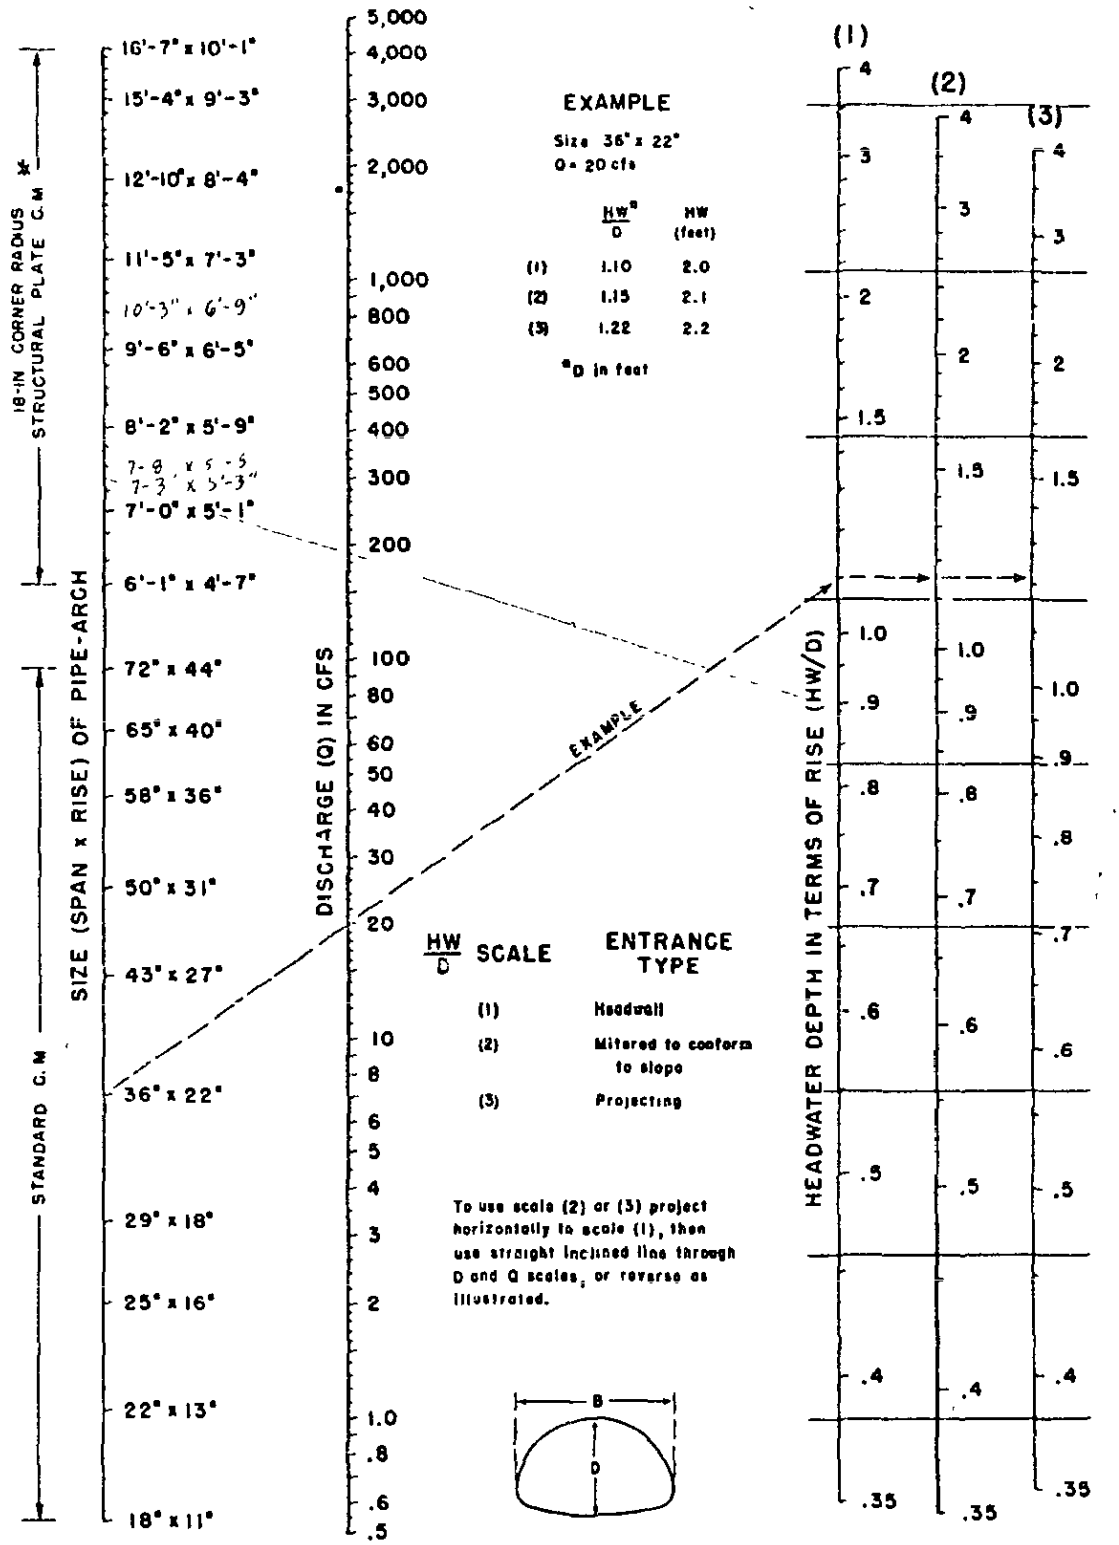
HW Elev $= 891.6 + 4.37 = 895.97$

4-8-76 WCR

Solution as an equivalent Pipe Arch

7'-3" x 5'-3" Area = 31 ft²

7'-8" x 5'-5" Area = 33 ft²



Assume point on inlet control nomograph equidistant between above pipe will equal a pipe arch of 32 ft².

$$\frac{HW}{D} = .89$$

$HW = .89 \times 4.95 = 4.41 \approx 4.37$

HW Elev = 8916 + 4.41 = 896.01 (USE)

HYDRAULIC ANALYSIS

Introduction

The river being studied is the Clinton River in the City of Pontiac, Oakland County, Michigan. The study limits are from the eastern corporate limit of the city at Opdyke Road upstream to Sylvan Lake. The flows used were determined using Brater's method and have been approved by the Michigan Department of Natural Resources. The hydraulic analysis of the Clinton River in the City of Pontiac was reviewed with Mr. Jan Persson, Senior Engineering Assistant, City of Pontiac. The project manager for this analysis was John Emig.

General Description of River

Because of its history of flooding, the Clinton River waterway in the City of Pontiac has been improved in several areas. In 1963, the section of the river through the downtown area of Pontiac was completely enclosed from west of Wide Track Drive to east of Union Street. This project is called the Clinton River Drain No. 1. The Drain No. 1 waterway consists primarily of twin concrete 10 ft. by 10 ft. box culverts with a 200 feet length of twin 11 ft. diameter concrete tubes used near the upstream end of the drain. Smooth transition sections are used between the different culvert types. The enclosed Drain No. 1 does not follow the route of the old Clinton River channel that was filled in (See Figure 1).

The 1965, the Drain No. 2 project consisted of improvements to the Clinton River waterway from the Drain No. 1 outlet near Union Street downstream to the eastern corporate limit of the city at Opdyke Road. To increase the flow capacity of the river, a straightened, excavated earth channel was constructed. Two portions of Drain No. 2 are concrete lined with vertical sidewalls. One area is downstream of the Drain No. 1 outlet for a distance of approximately 1600 feet and the other one is downstream of East Boulevard for approximately 1700 feet. The concrete-lined channels are 30 feet wide

with the height of the sidewalls varying from 10 to 12 feet. Steep channel slopes at the upstream ends of the concrete-lined areas are used to increase the flow velocity. At the downstream ends, drop structures with concrete aprons are used to reduce flow velocities before the flow enters the earth channel portions of the waterway.

The Clinton River Drain No. 3 project was completed in summer, 1977, and included improvements to the river waterway from the outlet of Crystal Lake downstream to the inlet of Drain No. 1 (See Figure 2). Some dredging was done on Crystal Lake. The Drain No. 3 system consists of an open channel waterway and a series of underground culverts. The open channel is connected to the enclosed portion at three points along the open channel reach. The first inlet is at the Crystal Lake outlet and consists of an Amil constant upstream level gate (Model D500). A 30 ft. wide weir alongside the gate diverts part of the flow to the open channel portion of Drain No. 3. The gate is designed to maintain the Crystal Lake water-surface at a constant level while passing a variable flow to an underground 10 by 11 ft. concrete box culvert. The remaining flow from the lake (normally constant) goes over the weir and enters the open channel portion. From Crystal Lake downstream to river mile 48.967, the open channel has been widened and deepened. At river mile 48.933, an inlet structure is located to permit part of the flow in the open channel to be diverted to an underground concrete 10 by 11 ft. box culvert. This culvert runs out to Bagley Street and then runs parallel to the culvert from the Amil gate. The two parallel culverts are connected by openings in the dividing wall to permit flow equalization. The remaining flow in the open channel continues on to the final inlet near the southwest corner of Bagley Street and Orchard Lake Avenue. The flow from the Bagley-Orchard Lake inlet enters the enclosed portion of Drain No. 3 through a 60 inch diameter concrete pipe. At this point, Drain No. 3 is completely enclosed in twin 10 by 10 ft. concrete box culverts and enters Drain No. 1 at the point of the old Drain No. 1 inlet. Construction plans for structures are shown in Appendix C.

From Crystal Lake upstream to Sylvan Lake, the Clinton River channel has not been improved. At river mile 51.078 is an earth and concrete dam called Dawson's Dam. The pond formed behind the dam is Dawson's Millpond. The dam is operated with a series of five sluice-underflow gates to vary the flow through the dam.

Cross Section Data Acquisition

Much of the Clinton River waterway in the City of Pontiac has been improved with some portions being concrete-lined or enclosed. The improved areas include

Clinton River Drains Number 1, 2 and 3. For Drains No. 1 and 2, channel and overbank information was obtained from as-built plans developed by Jones & Henry Engineers, Ltd., Toledo, Ohio (dated 1963 and 1965, respectively). Channel and overbank information for the improved areas of Drain No. 3 was obtained from construction plans also developed by Jones & Henry Engineers, Ltd., (1975). For the unimproved areas of the Clinton River, field-surveyed cross sections obtained by Johnson & Anderson, Inc., were used in the analysis. The date of this field survey was November, 1976.

Methods of Analysis

Water-surface profiles were computed using the COE HEC-2 step-backwater computer program. Bridges that were under low flow conditions for all four flows were coded according to the "normal bridge" routine requirements. For those bridges that experienced pressure or weir flow for any of the four flows, the "special bridge" routine was used to determine the upstream water-surface elevation.

The hydraulic model was developed for the 100-year flow. In the unimproved portions of the Clinton River, valley sections upstream and downstream of bridges were located where full cross section flow would be developed out of the bridge constriction. The criteria for placement of these sections was that outlined on pages 18-21 of the HEC Training Document No. 6, Application of the HEC-2 Bridge Routines. Accordingly, the downstream section was placed at a distance of about four times the average length of the side constriction caused by the bridge. The upstream section was at a distance about equal to the constriction. If additional sections were found necessary within this distance, the intermediate sections were encroached as appropriate. The same reasoning was used in modeling natural constrictions in the floodway.

The enclosed portions of the Clinton River system in the City of Pontiac were analyzed by hand using Manning's equation to determine losses.

Several high water marks had been recorded for the Clinton River in the City of Pontiac, however, because of the changes in the river and the improvements made they could not be used in this study.

Note that high water data not applicable

When was study Drain completed ?

Special Situations

The floodway for Drain No. 2 is within the river banks except for the initial 1300 feet of reach length west of Opdyke Road. This is the only portion of Drain No. 2 that requires the use of encroachments. The floodway for this area is encroached to expand at an angle of approximately 15° on both sides downstream from the point where the floodway is within the river banks. The concrete-lined area downstream of East Boulevard on Drain No. 2, because of its relatively steep slope and low friction, causes critical depth to be assumed by the HEC-2 program for this reach. Supercritical flow is possible for the concrete-lined area because the channel slope is steeper than critical for the flows used. However, the critical depth profiles obtained are conservative and are used for clarity in the Final Flood Insurance Study. This approach was approved in conversation with Dan Morgan of the MDNR. The drop structure used at the downstream end of the concrete-lined area returns the flow to subcritical conditions before entering the earth portions of the waterway. See Appendix D for calculations.

During the floods of the return periods examined, the Amil gate at the Crystal Lake outlet cannot keep the lake at the design level and reaches its maximum flow capacity of about 600 cubic feet per second. The remaining flood flow goes over the weir and enters the open channel portion of Drain No. 3. During the flood events, the weir is submerged.

The division of flow for the other two inlets on the open channel was analyzed as an island situation as described on page 320 of Open-Channel Hydraulics by Ven Te Chow. It was assumed that critical depth would occur at the inlet structures because of the drop of several feet in the invert elevation inside of both inlets. To support this assumption, Drain No. 1 and the enclosed portions of Drain No. 3 were analyzed to show that the back-water effects would not interfere with critical depth occurring at the Bagley-Orchard Lake and the intermediate inlets. Refer to Appendix E. A HEC-2 program was then started at the Bagley-Orchard Lake inlet at critical depth with assumed flow values and was run up to the intermediate inlet to obtain energy grade elevations at that point. A curve of flow rate versus energy grade elevation was then constructed for the channel cross section at the intermediate inlet. The intermediate inlet was analyzed as a weir in order to generate

Refer to Appendix F.

another curve of flow rate versus energy grade elevation. After the correct flows for each part of Drain No. 3 were determined, a HEC-2 program was started at the Bagley-Orchard Lake inlet and run up to the weir at Crystal Lake. An X5 card was used at the intermediate inlet to input the exact water-surface elevations at that point. The water-surface elevations obtained at the weir at Crystal Lake were below the lake elevations obtained by analyzing only the gate and weir showing that the Drain No. 3 open channel does not control the lake elevations. Refer to Appendix 6.

Dawson's Dam upstream of Crystal Lake was input into the HEC-2 program as a special bridge. The dam gates were coded as being in the fully open position. The bridge opening and width were input on the SB card as infinitely small values to force the special bridge routine to use weir flow only.

Hydraulic computations upstream of Dawson Mill Pond Dam were begun with the assumed starting condition of all gates fully open. This assumption is reasonable since there is no established operating policy, and since this would be a reasonable operating policy for the 100 year event based on the increased hydraulic capacity downstream with the completion of the Clinton River Drain No. 3 project. This analysis has determined that the Clinton River system through Pontiac can handle the 100 year event without flooding adjacent property. The hydraulic computations begun at the dam were carried to the upstream valley section at Sylvan Lake.

The final Flood Insurance Study profiles would reflect these computations except in the backwater of the dam where the mean dam elevation would be extended horizontally upstream until all four flow-profiles were intersected. The mean dam elevation (928.09) was computed using Oakland County Drain Commission weekly lake level reports for the period February 26, 1969 - July 29, 1977 (454 readings). A horizontal extension of mean dam was chosen as representative since, with the improved channel downstream, it would be reasonable operating policy to maintain a constant pool elevation with the mean elevation a reasonable choice.

NO

The hydraulic profiles will be adopted in the Flood Insurance Study through to Sylvan Lake. The flood frequency elevations for Sylvan Lake will be the flood frequency elevations developed hydraulically at the upstream valley section.

Consideration was given to establishing the Sylvan Lake flood levels based on a statistical analysis of the Cass Lake gage adjusted for the loss occurring between Cass Lake and Sylvan Lake. However, since a hydraulic analysis of the reach between Cass Lake and Sylvan Lake would not be contracturally feasible, and since assumed losses as reported in Brater's report[1] would be based in part on past operating policies at Dawson Dam, it seemed more reasonable to assume flows as presented in Brater's report and to base Sylvan Lake elevations on the hydraulic capacity of the channel between Sylvan Lake and the Dawson Dam.

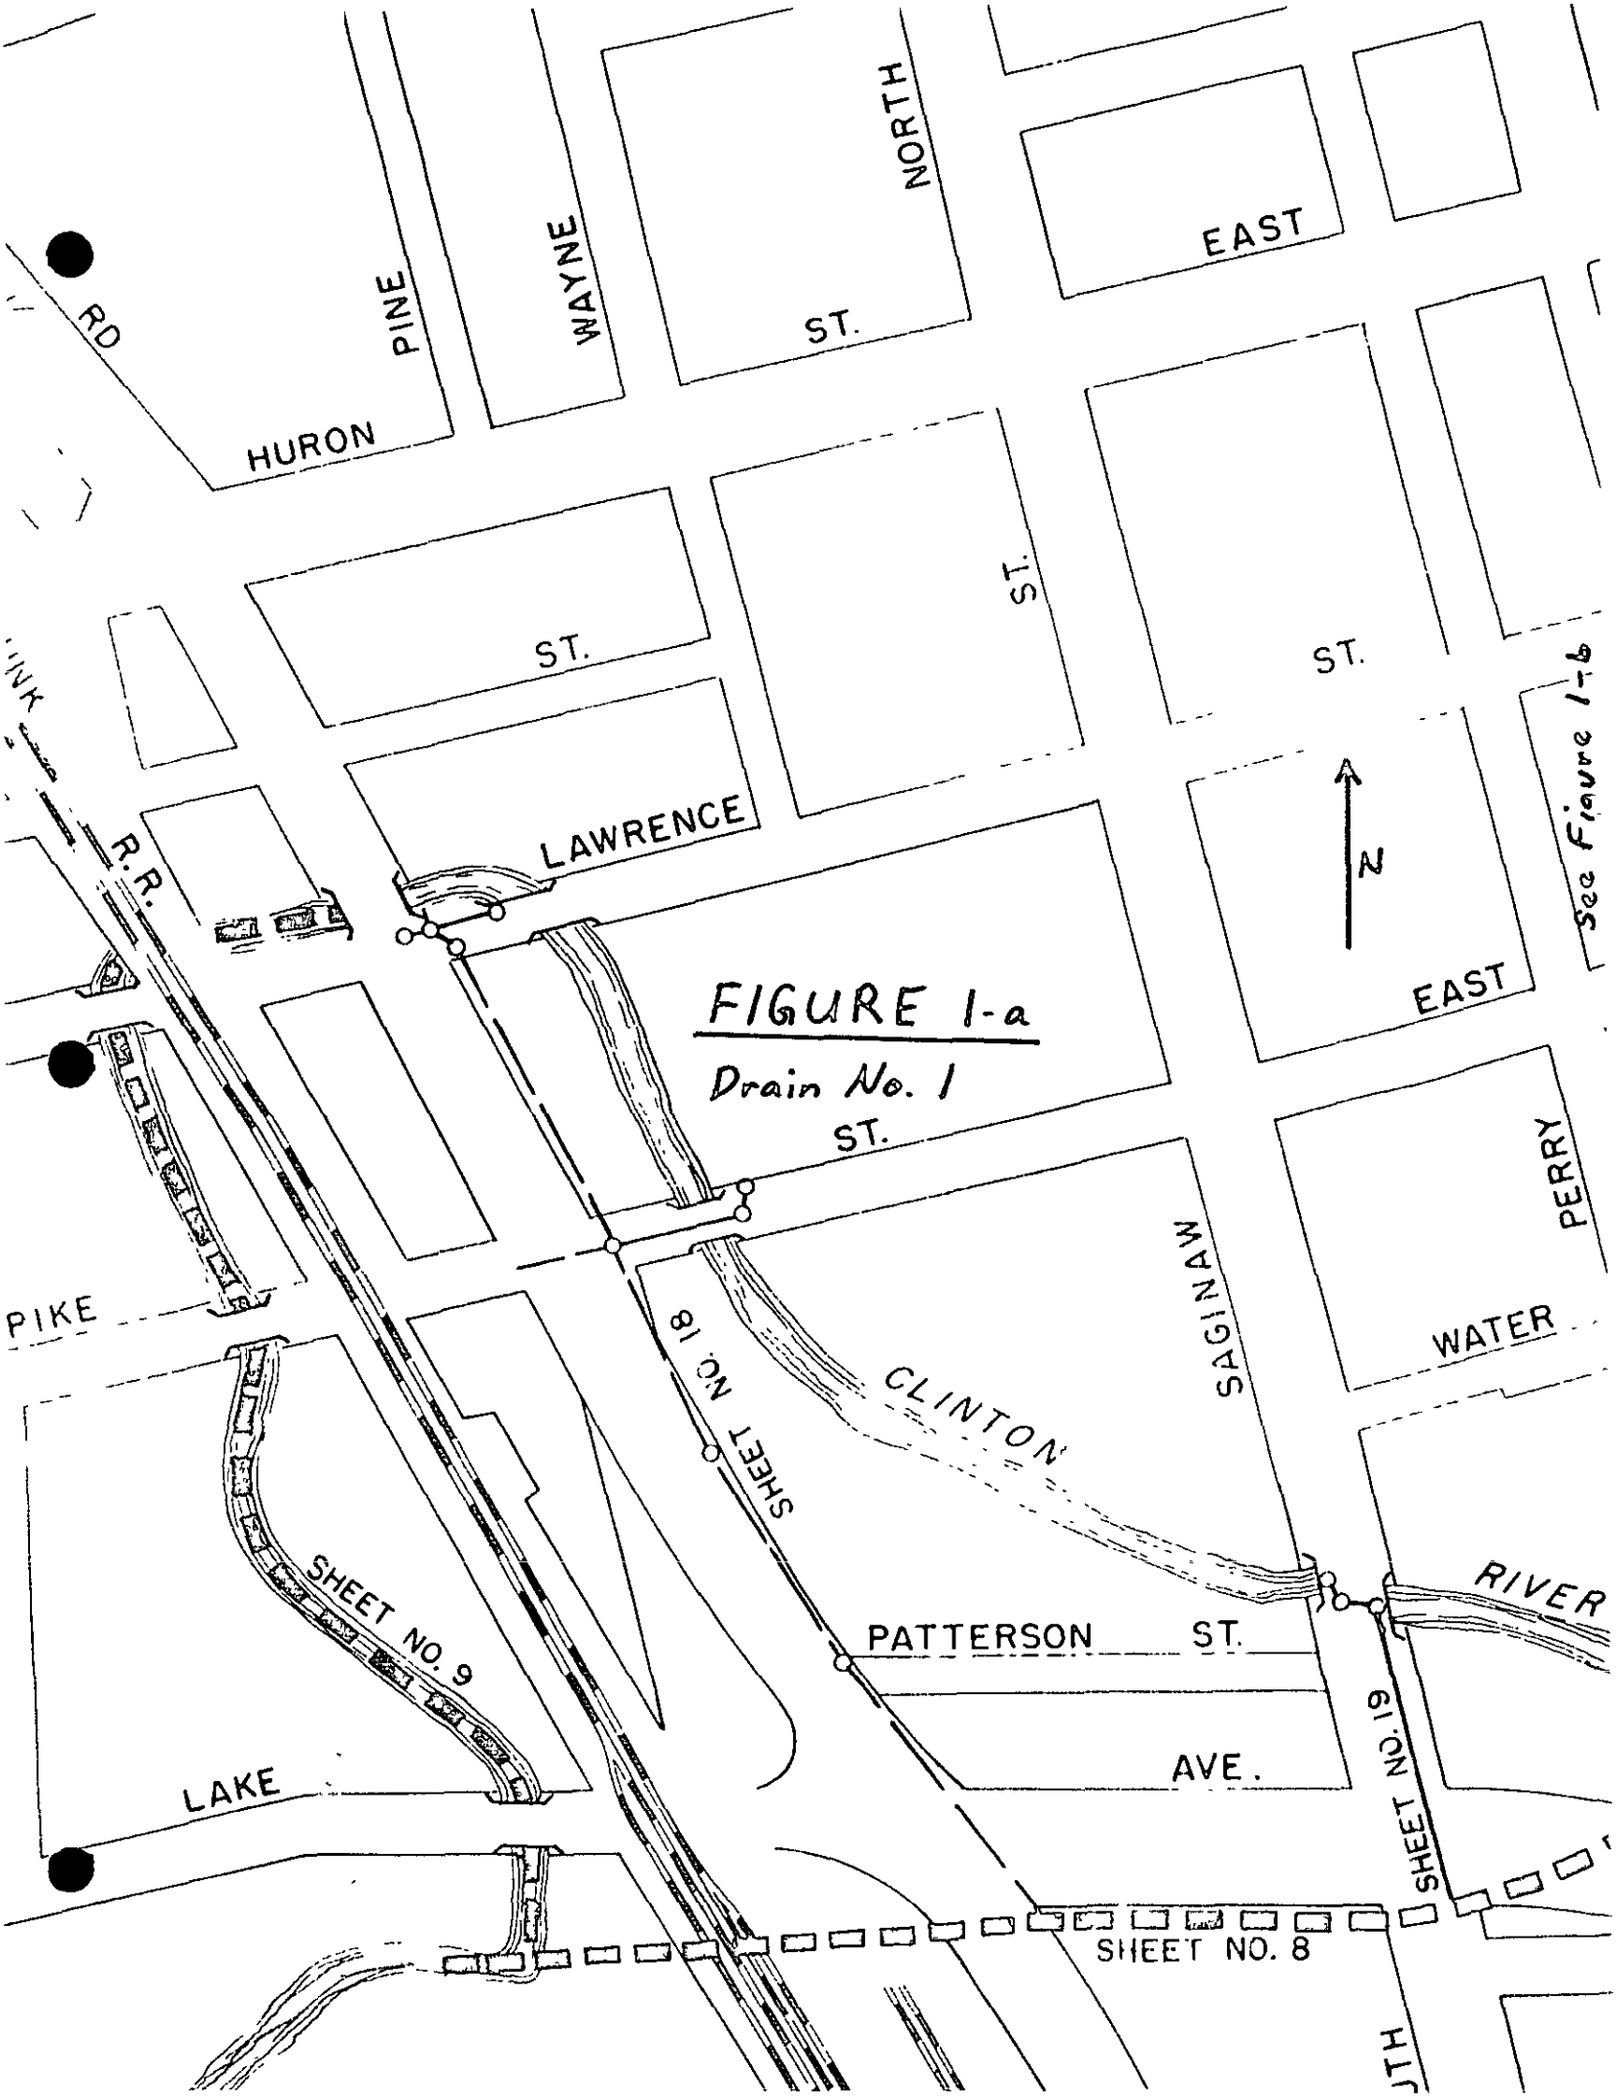
Starting Points

Clinton River Drain No. 2 water-surface profiles begin at Opdyke Road at the eastern corporate limit of the City of Pontiac. The HEC-2 run starts using water-surface elevations for the 10-, 50-, 100- and 500-year floods from the Pontiac Township study (submitted to MDNR August 12, 1977) as known water-surface elevations.

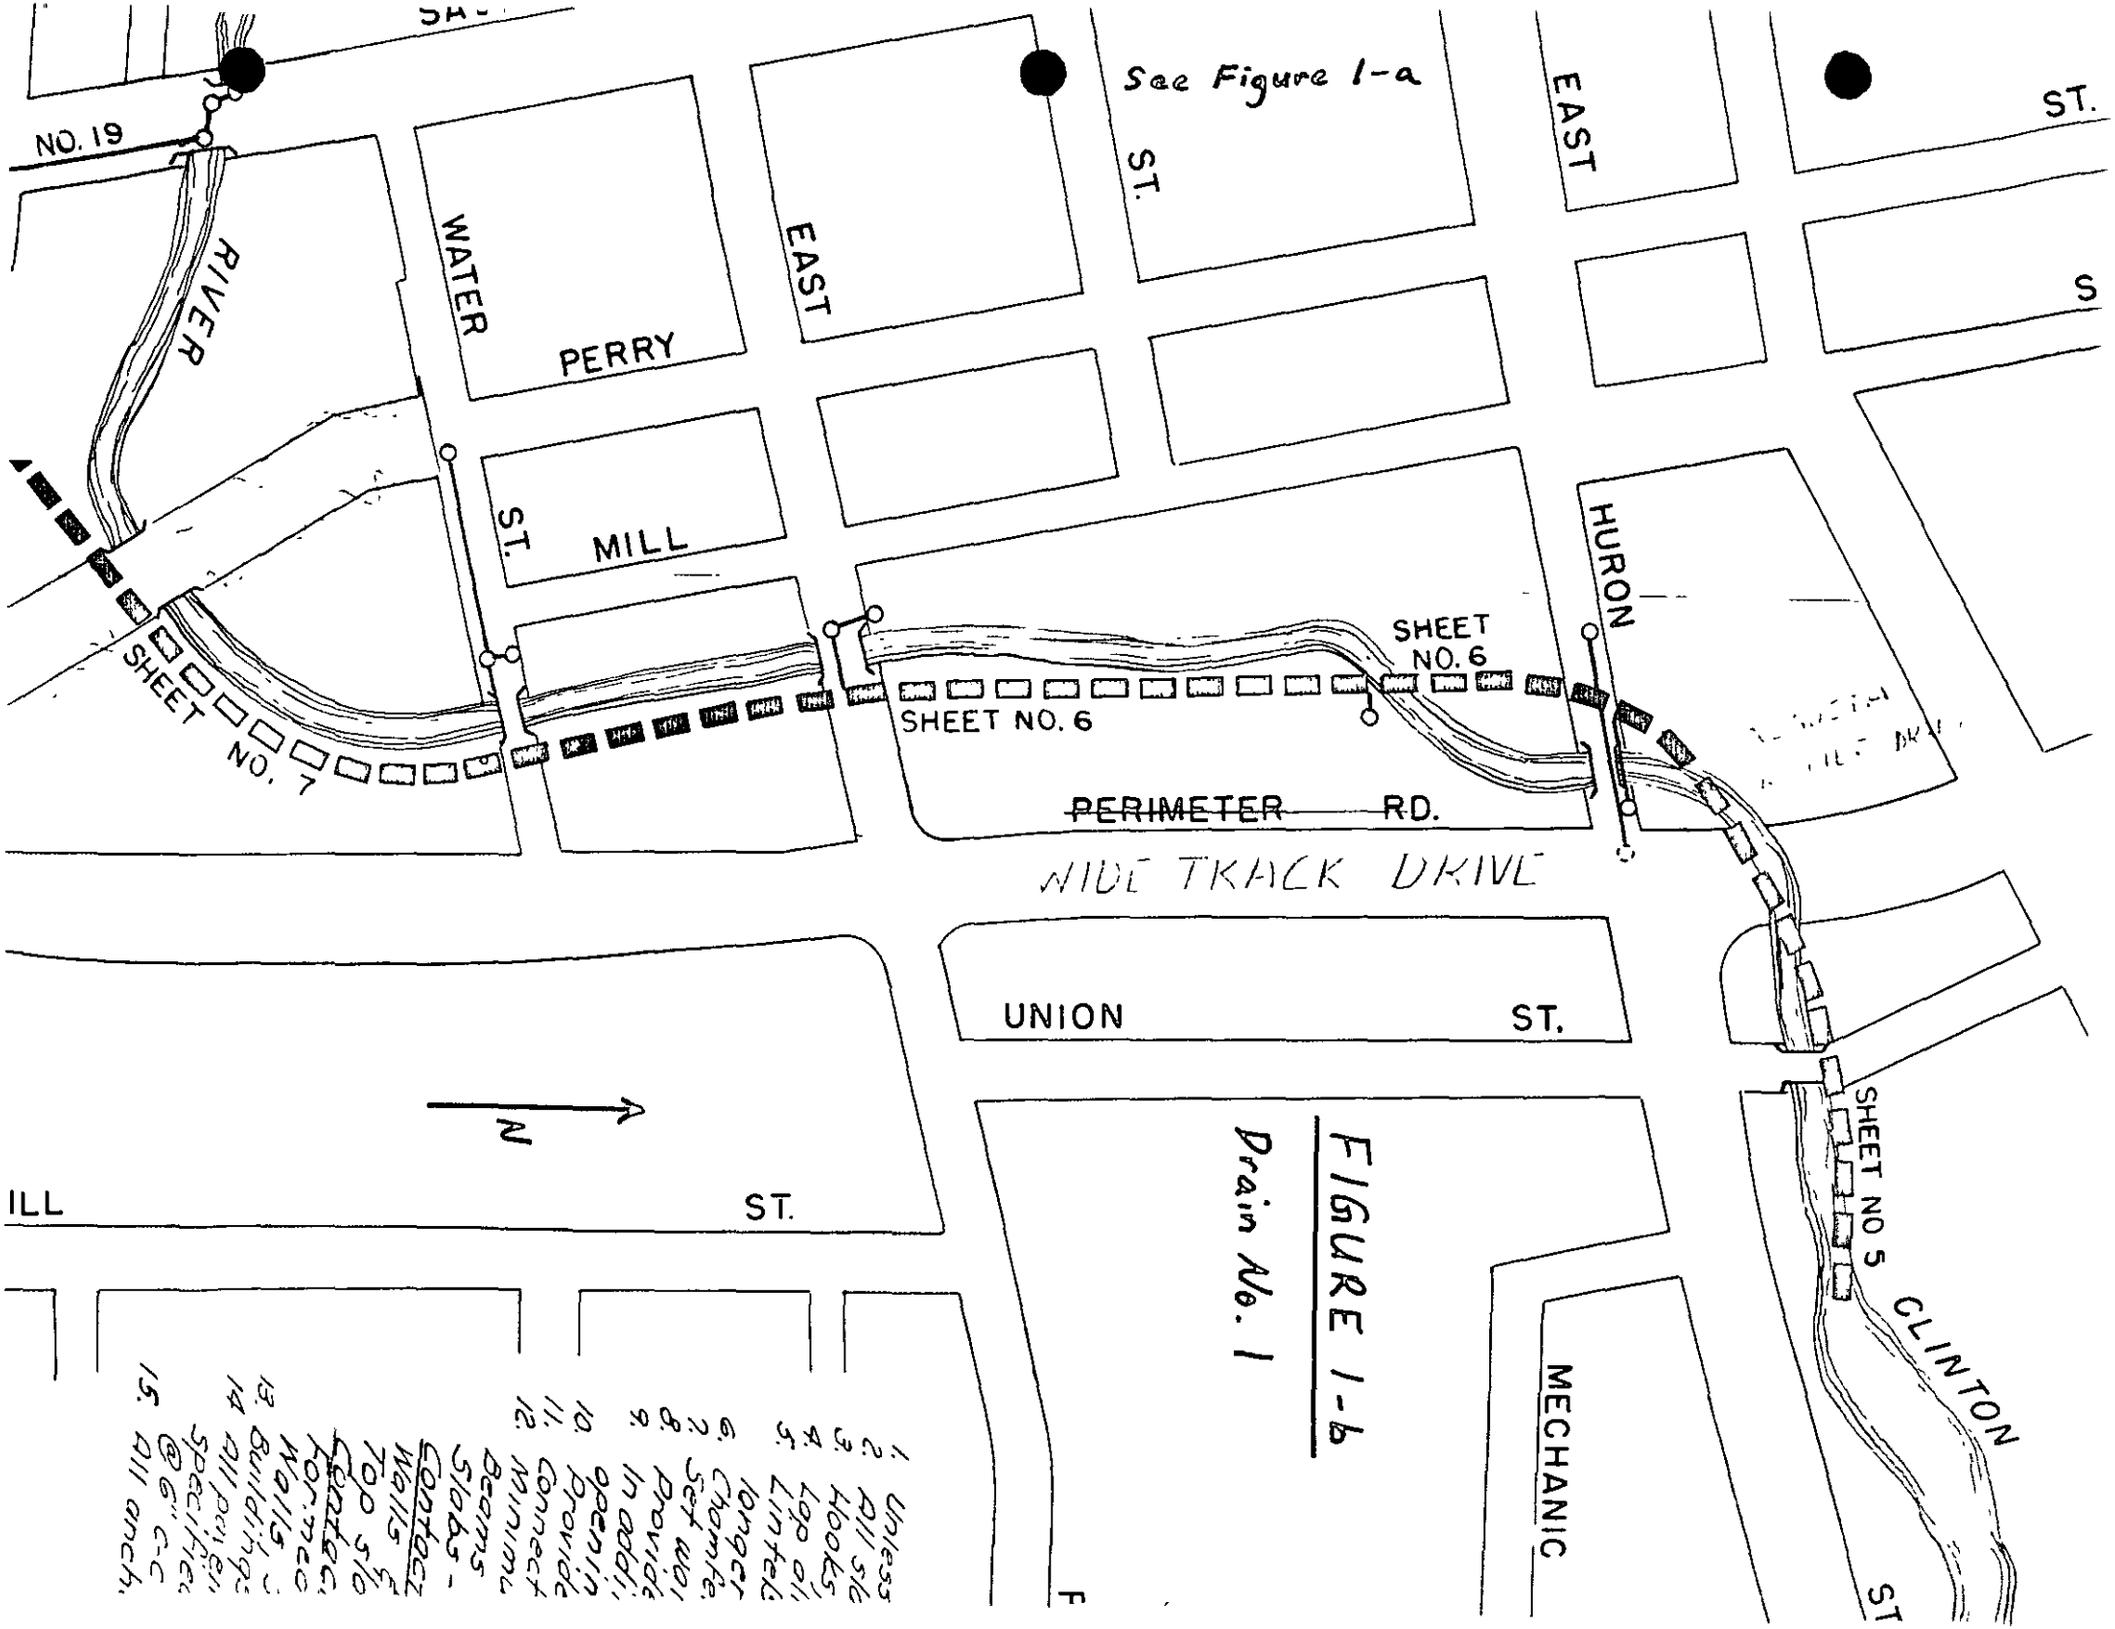
Clinton River Drain No. 3 water-surface profiles begin at the Bagley-Orchard Lake inlet at critical depth for each flood flow. The water-surface profiles for the section of the Clinton River upstream of Crystal Lake are started at the lake elevations for the 10-, 50-, 100- and 500-year floods.

Variables and Coefficients

The roughness factors (Manning's "n") were established by comparing photographs and field inspection with the photographs and descriptions found on pages 101 to 123 in Open-Channel Hydraulics, by Ven Te Chow, as well as with photographs and descriptions found in the geological Survey Water-Supply Paper 1849, Roughness Characteristics of Natural Channels.



[1] "A Study of Flood Conditions along the Clinton River in the Region Which Includes the Western Part of Pontiac, Waterford Township, and West Bloomfield Township", E. F. Brater, March 4, 1976.



In general, the following range of values were used:

	Description	Manning's "n"
1.	Channel	
a.	Concrete lined, excellent condition	.012
b.	Excavated, clay bottom, no debris	.020 - .024
c.	Excavated, clay bottom, light debris	.025 - .026
d.	Natural channel, clay bottom, moderate debris, brush	.028 - .035
e.	Natural channel, heavy debris and brush	.038 - .044
2.	Flood Plains	
a.	Short grass, little or no weeds and debris	.030 - .035
b.	Tall grass, weeds, light brush	.038 - .045
c.	Moderate to heavy brush, some debris	.048 - .055
d.	Very dense brush, some debris	.070 - .100

Because of the very smooth transitions and alignment of the Clinton River Drain No. 2, the contraction and expansion coefficients used for this portion of the river were .1 and .2, respectively. For all other parts of the Clinton River, the coefficients used were .3 for contraction and .5 for expansion.

The loss coefficients used in the HEC-2 "special bridge" routine were determined as outlined in exhibit 2 of the HEC-2 Users Manual.

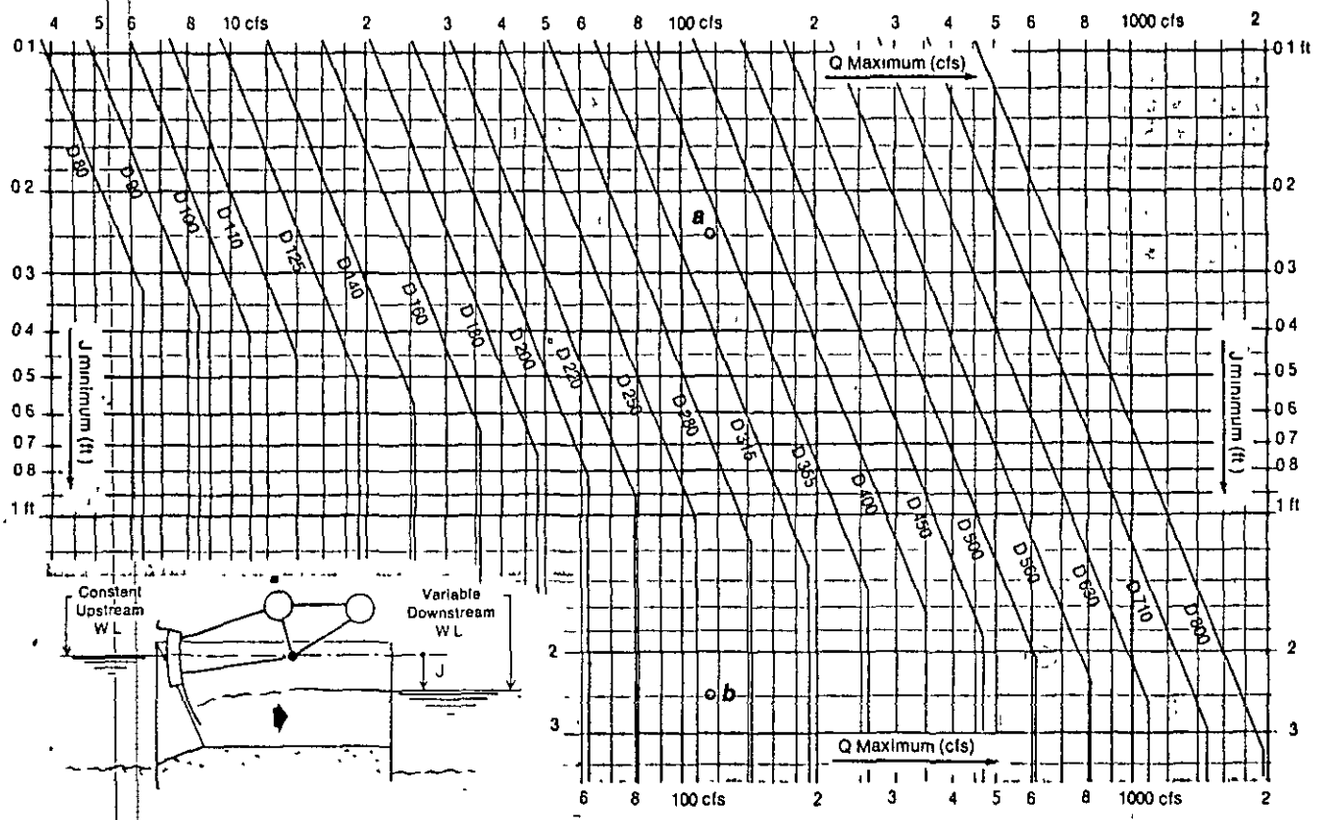
APPENDIX C



AMIL gates are manufactured in 21 standard sizes, designated AMIL D80, AMIL D90 .. up to AMIL D800

SELECTING YOUR AMIL GATE

Plot on the chart below the point corresponding to:

1. *Maximum discharge* Q_M to be handled at the gate
2. *Minimum head differential* J_m available at maximum discharge for the equipped structure

Find the proper gate size on the first black line to the right of this point.

GATE SIZE SELECTION CHART

Hydraulic Data based on *TRANOR* Standard Structure* (see next page)

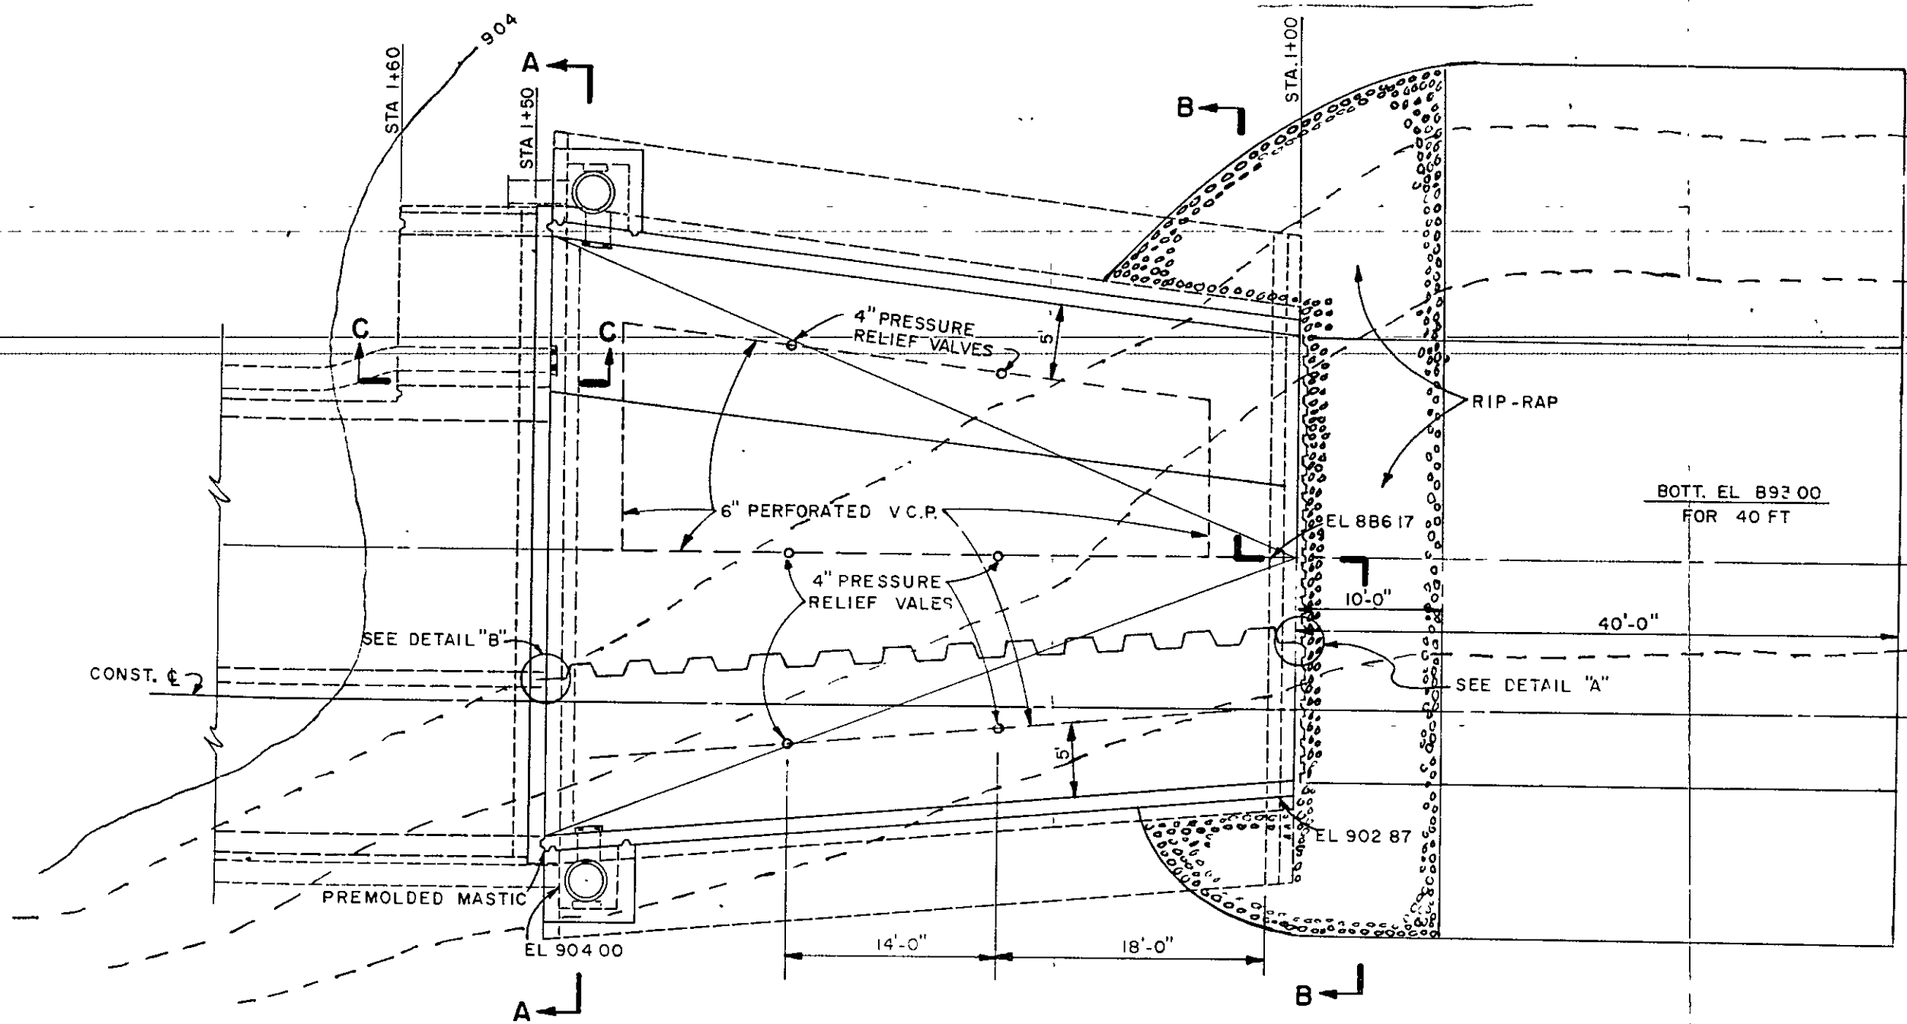
Example 1:

The water level must be kept constant at elevation 54 00 ft in a canal, at a location where the maximum discharge is 115 cfs Maximum tailwater elevation is 53 75 ft Which gate is suitable?

The minimum head differential available for the equipped structure is $J_m = 54\,00 - 53\,75 = 0\,25$ *ft Point* **a** *on the chart corresponds to* $Q_M = 115$ *cfs and* $J_m = 0\,25$ *ft The suitable gate size is the AMIL D355*

Note that for a head differential of 0 25 ft, the AMIL D355 capacity is 124 cfs

Example 2:



The free surface elevation of a lake has to be maintained constant The maximum discharge at the outlet is equal to 115 cfs and the drop is 2 50 ft Which gate is suitable?

Point **b** *on the chart corresponds to the above data and the suitable gate size is now the AMIL D280*

Note that the AMIL D280 has a maximum capacity of 142 cfs.

Two or more AMIL gates can be installed side by side (in parallel) to increase capacity, to reduce head differential or to better match structure and site

BY Rob DATE 6-3-22 JOB DESCRIPTION Critical Slope Calc SHEET 2 OF 2
SUBJECT Clinton River Div. 6.2 JOB NO. 5620-06-1

For the 50 yr. flood: $Q = 3250$ cfs

$d_c = 7.62$ ft.

$A_c = 228.6$ ft.^{2} $R_c = 45.2$ ft.

$$S_c = \left[\frac{0.012(3250)}{1.49(228.6)(45.2)^{2/3}}\right]^2$$

$S_c = 0.000081 = 0.0081\% < 0.30\%$

For the 100 yr. flood $Q = 3720$ cfs

$d_c = 8.29$ ft.

$A_c = 248.7$ ft.^{2} $R = 46.6$ ft. $R_c = 5.34$

$$S_c = \left[\frac{0.012(3720)}{1.49(248.7)(46.6)^{2/3}}\right]^2$$

$= 0.00156$

$S_c = 0.000087 = 0.0087\% < 0.30\%$

0.156%

For the 500 yr. flood $Q = 5110$ cfs

$d_c = 10.12$ ft.

$A_c = 303.6$ ft.^{2} $R_c = 50.2$ ft.

$$S_c = \left[\frac{0.012(5110)}{1.49(303.6)(50.2)^{2/3}}\right]^2$$

1.68%

$S_c = 0.000099 = 0.0099\% < 0.30\%$

Channel slope is steeper than critical slope for all flows

$R = 2.75$ ft

$A = 190.07$ ft^2 ; $\Rightarrow \frac{V^2}{2g} = 1.99$ ft ; $L = 190$ ft.

$h_f = \frac{29.1 n^2 L}{R^{4/3}} \frac{V^2}{2g} = 0.41$

$H = 909.59 + 0.41 = 910.0$ ft (HGL = 908.01 ft)

5. At Section 48.393 : (Q = 1730 cfs) (Transition zone)

$d = 10.0$ ft

$R = 2.5$ ft

$A = 200$ ft $\Rightarrow \frac{V^2}{2g} = 1.16$ ft ; $L = 24$ ft.

$h_f = 0.03$ ft

h_t (transition loss) $= 0.15 \frac{V^2}{2g} = 0.17$ ft

$H_T = 910.0 + 0.03 + 0.17 = 910.20$ ft. (HGL = 909.04 ft.)

6. At Section 48.420 : (Q = 1730 cfs)

$d = 10.0$ ft

$R = 2.50$ ft

$A = 200$ ft $\Rightarrow \frac{V^2}{2g} = 1.16$ ft. ; $L = 143$ ft.

$h_f = \frac{29.1 n^2 L}{R^{4/3}} \frac{V^2}{2g} = 0.21$ ft

$H = 910.20 + 0.21 = 910.41$ ft. (HGL = 909.25 ft)

7. At Section 48.538 (Q = 1730 cfs)

d = 10.0 ft.

R = 2.50 ft

A = 200 ft^2 $\Rightarrow \frac{V^2}{2g}$ = 1.16 ; L = 622 ft.

h_f = 0.89 ft

H = 910.41 + 0.89 = 911.30 ft. (HGL = 910.14 ft)

8. At Section 48.540 (Q = 1650 cfs)

d = 10.0 ft

R = 2.50 ft

A = 200 ft^2 $\Rightarrow \frac{V^2}{2g}$ = 1.06 ft ; L = 10 ft.

h_f = 0.01 ; bent loss ; $h_b = 0.45 \frac{V^2}{2g}$ = 0.47 ft

H = 911.30 + 0.01 + 0.47 = 911.78 ft (HGL = 910.72 ft.)

9. At Section 48.757 (Q = 1650 cfs)

d = 10.0 ft

R = 2.50 ft

A = 200 ft^2 ; $\Rightarrow \frac{V^2}{2g}$ = 1.06 ft ; L = 1146 ft.

h_f = 1.50 ft

H = 911.78 + 1.50 = 913.28 ft. (HGL = 912.22 ft)

10. At Section 48.764 (Q = 600 cfs)

d = 10.0 ft

A = 110 ft ; P = 42 ft.

R = 2.62 ft ; L = 37.5 ft ; $\frac{V^2}{2g}$ = 0.46

h_f = 0.02

h_t (Trasition) = $0.5 \frac{V^2}{2g}$ = 0.23

$\Rightarrow H = 913.28 + 0.02 + 0.23 = 913.53$ ft.

(HGL = 913.07 ft)

At Section 48.768 ($Q = 600$ cfs)

$d = 10.0$ ft

$A = 110$ ft ; $\frac{v^2}{2g} = 0.46$ ft ; $L = 20$ ft.

$R = 2.62$ ft

$S_f = 0.01$

$H = 913.53 + 0.01 = 913.54$ ft. (HGL = 913.08 ft.)

12. At Section 48.957 ($Q = 600$ cfs)

$d = 10.0$ ft.

$A = 110$ ft $\longrightarrow$ $\frac{v^2}{2g} = 0.46$, $L = 1000$ ft.

$R = 2.62$ ft.

$S_f = 0.53$

$H = 913.54 + 0.53 = 914.07$ ft. (HGL = 913.61 ft).

$Q = 85$ cfs

$D = 5'$ concrete $\quad A = \frac{\pi}{4}R^2 = 19.635 \text{ ft}^2 \Rightarrow v = 4.33$ ft/sec

$L = 160'$ $\quad \rightarrow \frac{v^2}{2g} = 0.29$ ft

$n = 0.012$

$R = 1.25'$

$$h_f = \frac{29.1 n^2 L}{R^{4/3}} \frac{v^2}{2g} = 0.14 \text{ ft}$$

$$h_e = 0.4 \frac{v^2}{2g} = 0.12 \text{ ft}$$

$H_T = 0.26$ ft.

Net weir opening - 45 ft.

Reduction in weir length due to 12 side contractions

$$L = L' - 0.1NH \quad ①$$

$$L = 45 - 0.1(12)3$$

$$L = 41.4 \text{ ft.}$$

Computation of weir coefficient, C

$$C = 3.27 + 0.40 \frac{H}{h} \quad ①$$

$$C = 3.27 + 0.40 \frac{3}{3}$$

$$C = 3.67$$

H = head on weir
h = height of weir
H = 3 ft. } estimated values
h = 3 ft. }

① From: Ven Te Chow, Open-Channel Hydraulics, p. 362

$$Q = CLH^{3/2}$$

$$H = \left(\frac{Q}{CL}\right)^{2/3}$$

$$H = \left[\frac{600}{3.7(41.4)}\right]^{2/3}$$

$$H = 2.48$$

Sensitivity of C Value

@ Q = 600

@ C = 3.0 H = 2.86

@ C = 4.0 H = 2.36

Intermediate inlet crest @ elev. 912.00

EGL @ Inter. Inlet = 912.00 + 2.48 = 914.48

Other values in table on previous page calculated similarly.

The headloss caused by the bars on the inlet structures was examined as shown below.

Bars are: 6" long x ½" wide x 69" high Flat Face
Spacing: 6" center to center.

from Kirschmer: $h_L = \beta\left(\frac{w}{b}\right)^{4/3} h_v \sin\theta$ ②

where h_L = headloss

β = bar shape factor = 2.42 (P. 276 of ②)

w = maximum cross-sectional width of bars facing flow, ft.

b = minimum clear spacing of bars, ft.

h_v = velocity head of flow approaching rack, ft.

θ = angle of rack with horizontal

② from Metcalf & Eddy, Inc. Wastewater Engineering, p. 275

$h_v = 0.01$ (from HEC-2 @ $Q = 80$ cfs)

$h_L = 2.42 \left(\frac{.042}{0.5}\right)^{4/3} (0.01)(1)$

$h_L = 0.0009$ ft. insignificant due to relatively wide spacing of bars.

Using the values in the table, Curves ① and ② were plotted. Curve ② was used to determine the flow division for each flood event. Curve ① was used as a check for the 100-year flow only.

City of Pontiac
Flood Insurance Study
Clinton River from
Orchard Lake Rd to
Sylvan Lake

Profile sensitivity to
Dam Operating Policy.
Policy analyzed = 4 gates half
open, one gate closed entirely
