MICHIGAN DEPARTMENT OF ENVIRONMENTAL QUALITY WATER RESOURCES DIVISION APRIL 2015

STAFF REPORT

BIOLOGICAL SURVEY OF THE CHERRY CREEK AND PIGEON RIVER WATERSHEDS HURON AND SANILAC COUNTIES, MICHIGAN JUNE-AUGUST 2013

INTRODUCTION

During summer 2013, staff of the Michigan Department of Environment Quality (MDEQ), Water Resources Division (WRD), assessed biological, chemical, and habitat conditions in watersheds in Huron and Sanilac Counties in eastern Michigan. The watershed group was comprised of the Pigeon River and Cherry Creek watersheds. The objectives of the investigation were to:

- 1. Assess the current status and condition of individual water bodies and determine whether Michigan Water Quality Standards (WQS) are being met, using a probabilistic sampling design.
- 2. Identify nonpoint sources (NPS) of water quality impairment, and evaluate the effectiveness of specific NPS water quality improvement projects.
- 3. Satisfy monitoring requests submitted by internal and external customers.
- 4. Determine if the water quality is changing over time.

Watershed Group Description

The Pigeon River and Cherry Creek watersheds are coastal watersheds located primarily in Huron and Sanilac Counties with small portions extending into Tuscola and St. Clair Counties. The Pigeon and Pinnebog Rivers are the largest systems, with both streams having main channel lengths of approximately 40 miles. In addition to these rivers there are numerous smaller systems that drain directly to Lake Huron or Saginaw Bay. The watersheds are wholly within the Huron/Erie Plains Ecoregion (Omernik and Gallant, 1988).

Soil composition within the watersheds consists mostly of soil types that are nearly level and gently undulating and either somewhat poorly drained or poorly drained (United States Department of Agriculture [USDA], 1980). The combination of these attributes yields systems with minimal groundwater influence, which are predominantly influenced by precipitation events.

Land use in the sampled watersheds is predominantly agricultural (82.5% in Huron County and 67.7% in Sanilac County) (USDA, 2007). Many of the smaller streams in the watersheds have been straightened and dredged to accelerate surface drainage. Many of the sites sampled were maintained drains with herbaceous vegetation dominating the banks, no canopy cover, and crop land a short distance from the top of the maintained bank.

Previous MDEQ sampling efforts were conducted in June 2008 (Cooper, 2009), June-August 2003 (Cooper, 2004), June-July 1998 (Walterhouse, 1999a and 1999b), 1993 and 1994 (Morse, 1994 a-d), and 1991 (Morse, 1992). Each of the sampling efforts reported varying degrees of impairment to the biological community. The high percentage of agricultural land use was cited as the chief cause of impairment. Specifically, extensive channel alteration, excessive

siltation/sedimentation, lack of stable substrate, scoured banks, and insufficient riparian habitat. Several sites also had nuisance aquatic plant/algae conditions suggesting nutrient enrichment.

METHODS

Biological (macroinvertebrate) and habitat surveys were conducted using the Surface Water Assessment Section (SWAS) Procedure 51 (MDEQ, 1990). A total of 31 sites were sampled during 2013. To develop a statistically-based estimate of attainment status in the Cherry Creek and Pigeon watersheds, 26 randomly selected stream/river sites were assessed. Four previous status sites were sampled to determine temporal trends within the watershed group. One additional site was targeted for sampling based on a request from the United States Environmental Protection Agency (USEPA) to inform a planned nutrient Total Maximum Daily Load for the watershed. Both the macroinvertebrate and habitat components of Procedure 51 were performed at all 31 sites (Figure 1 and Table 1). In addition, water samples were collected at one station, and a few locations were visited and subject to only visual observation. This study was designed to provide statistically sound conclusions on the status and condition for the entire area sampled (both watersheds) and not the individual watershed level. Assessment at the watershed level in this study may not possess sufficient statistical power, and any results and/or discussion at the individual watershed level should be considered with caution.

The biological and habitat data were analyzed using the methods outlined in Creal *et al.*, 1996. Macroinvertebrate communities were ranked from excellent to poor based on a scale from 9 to -9. A site score of +5 or greater is considered excellent, -5 or less poor, and -4 to +4 are classified as acceptable. Negative scores for acceptable sites are considered to be tending towards a poor ranking while positive acceptable scores are tending towards excellent. Ten metrics were measured to determine the habitat scores. The highest possible habitat score is 200. Sites with a score >154 are considered excellent, between 105 and 154 good, 56 to 104 marginal, and <56 poor.

RESULTS AND DISCUSSION

Current Status/Attainment of WQS

Benthic Macroinvertebrates

Of the 26 probabilistic sites, 18 (69% ± 8%) were supporting the Other Indigenous Aquatic Life designated use component of R 323.1100(1)(e) of the WQS. Percent attainment was calculated by dividing the number of random sites that met WQS by the total number of random locations (18/26 = 0.69). This value is coupled with a 95% confidence interval to provide our estimate of certainty, meaning there is 95% certainty that true proportion of attainment in sampled watersheds is within ± 8% of the 69% result. The mean Procedure 51 score for macroinvertebrates among the 26 randomly selected sites was -2.9. Total taxa numbers ranged from 12 to 29 at the probabilistic stations. The number of Ephemeroptera, Plecoptera, and Trichoptera families ranged from 0 to 9. Stoneflies were found in 6 of the 26 probabilistic sites. Eighteen sites in the watershed group supported the Other Indigenous Aquatic Life designation with macroinvertebrate scores ranging from +4 to -4, with 15 of these sites having negative scores. The remaining 8 randomly selected sites did not meet the criteria to support the Other Indigenous Aquatic Life designation. These sites and their corresponding scores were Big Creek (Site 5) score -5, Mill Creek (Site 7) score -5, Elkton Drain (Site 11) score -7, Gorke Drain (Site 12) score -6, Bird Creek (Site 15) score -6, Pigeon River (Site 18) score -7, Southworth Drain (Site 24) score -5, and County Line Creek (Site 25) score -8. Macroinvertebrate sampling results and metric evaluations for all sites sampled can be found in Table 2.

Habitat

Overall stream habitat quality was low at the probabilistic stations, with clear evidence of extensive habitat alterations at many sites. Of the 26 probabilistic sites surveyed for habitat, 2 were rated as excellent (8%), 6 were rated as good (23%), 13 were rated as marginal (50%), and 5 were rated as poor (19%). Lower habitat scores were mainly due to either poor or marginal scores in the following categories; sinuosity, pool variability, epifaunal substrate availability, flashiness, bank stability, vegetative cover, and riparian vegetative zone width. All five of the sites with poor habitat scores were highly modified to promote agricultural land use activities (Photo A). Habitat metric scores, ratings, weather, and stream conditions for all sites sampled are presented in Table 3.

Photo A: Upstream portion of Shebeon Creek (Site 13) the personification of a highly modified system. Note the slumping bank, which was rare.

Algae and Aquatic Plants

Nuisance aquatic algal/plant conditions were present at 4 sites sampled in the summer of 2013. Three of the 26 (11%) probabilistic sites (Shebeon Creek, Gorke Drain, and Baranski Drain) and one trend site (Columbia Drain) had nuisance conditions at the time of sampling with Cladophora coverage ranging from 60-85% (Table 4).

The presence of nuisance Cladophora at these sites does not necessarily indicate persistent summer-long nuisance conditions. Previous sampling of Michigan streams by SWAS staff has found that these blooms can come and go throughout the summer governed by physical and chemical conditions. Additionally, extensive riparian canopy removal and channel widening, with its resultant low flow velocities (both commonly associated with maintained agricultural drainage systems such as those sampled in the Cherry Creek/Pigeon River watersheds) results in the

stream receiving full sunlight for large portions of the day, which can promote primary production and stimulate nuisance conditions even without elevated nutrient concentrations. Additional monitoring of nutrients and expression permanence is needed to determine whether nutrient expression at these sites is a result of drain maintenance activities or likely due to increased loading of nutrients into the system.

Water Chemistry

A water grab sample was collected and analyzed for nutrients at one trend sample site during 2013. Columbia Drain (Site 1T) was sampled due to the extent of Cladophora growing in the sample reach (Photo B). All parameters met WQS (Table 5). The excessive algal growth is likely due to the combination of several factors, including availability of hard substrate (not common at other sample locations), lack of shade/canopy, and nutrient inputs directed from the adjacent field (Photo C).

NPS Water Quality Impairments

The majority of sites sampled in 2013 expressed some level of impairment from NPS activities associated with agriculture. Sixteen of the 31 sites were highly modified and regularly maintained to drain cropland. At these sites vegetated buffer zones were often undersized or lacking altogether (Photo D). In addition to insufficient buffer zones, outfalls from field tiles were also observed at some sites. The following sites were modified (dredged and canopy removal) to be categorized as drains; Cramp Drain (Site 4), Big Creek (Site 5), Nettle Run (Site 8), Shebeon Creek (Site 9), Elk Creek (Site 10), Elkton Drain (Site 11), Gorke Drain (Site 12), Shebeon Creek (Site 13), Bird Creek (Site 15), Baranski Drain (Site 21), Schram Branch (Site 22), Big Creek (Site 26A), Beaubien Drain (Site 28A), Wixon Drain (Site 30A), Columbia Drain (Site 1T), and Bad Axe Creek (Site 1R).

Monitoring Requests

Bad Axe Creek/Drain (Site R1)

At the request of the USEPA a sample site was added to Bad Axe Creek. Previous sampling of this site in 1998 found both the macroinvertebrate community and habitat to be poor. Results from the 2013 sampling effort also ranked the macroinvertebrate community as poor (-5) but the habitat as marginal (75). The 1998 study mentioned "extreme fluctuations in stream flow" as a problem for the highly channelized systems in the watershed (Walterhouse, 1999a). This site on Bad Axe Creek provided a great example of this during 2013. The initial attempt to sample the site on July 8 was after 3.71 inches of rain had fallen in the area the day before (National Oceanic and Atmospheric Administration [NOAA], 2013). Upon reaching the site it was clear that conditions were unsafe for sample collection (Photos E and F). The second visit to the site in August found the water level greatly reduced and favorable for sample collection (Photos G and H). The dramatic increase in water volume and flow during the July 2013 (and any similar) rain event are likely to have a negative impact on the macroinvertebrate community.

Temporal Water Quality Changes

Trend Sites

Sampling was conducted at four sites previously sampled in 2008 to elucidate temporal water quality trends within the watershed group. All four sites had acceptable macroinvertebrate scores (+2 to -2) and a range of habitat scores (188 to 99). Pinnebog River (Site 4T) scored excellent for habitat (188) and was the only trend site with a positive macroinvertebrate score (+2). The two sites with good habitat scores were Big Creek (Site 5T) and Elm Creek (Site 6T), which had macroinvertebrate scores of -2 and -1, respectively. Columbia Drain (Site 1T) had a marginal habitat score and a macroinvertebrate score of -2.

Comparing the 2013 and 2008 scores suggest a general trend of macroinvertebrate community improvement with static habitat quality (Figures 2a and 2b). However, there appears to be no correlation between changes in macroinvertebrate and habitat scores. The magnitude of change in the scores between the two sample years are minimal and may be attributable to natural variability. Additional sampling of these sites in future years should help to provide a clearer picture of the water quality trends in this watershed group.

Aquatic Invasive Species

Invasive species were observed at 6 of the 31 sampled sites with a total of 5 different species found (Table 6). Species observation was done during normal Procedure 51 survey time and neither intensive nor quantitative sampling was performed. Therefore, it is possible that additional invasive species were present but not observed at any or all of the sample sites. Overall densities observed during 2013 sampling in the watershed group were sparse.

CONCLUSIONS

The surveys performed during 2013 in the Pigeon River and Cherry River watersheds suggest that most sites (18 of 26) were rated as acceptable for macroinvertebrate community quality; many are being negatively impacted by agricultural undertakings. Stressors include; lack of suitable colonization habitat, channelization, riparian buffer loss, sedimentation, and flashy flows.
