Annual Detroit HIV Surveillance Report
New Diagnoses and Prevalence, 2015
All data as of May 1, 2016
Overview

Michigan's HIV Surveillance Program collects, interprets, and disseminates population level data regarding persons living with HIV (PLWH) and persons at risk of contracting the virus. Since 2001, the program has produced semi-annual reports for a wide audience. Beginning in 2016, these reports were overhauled and split into two parts. This report presents the most relevant information using graphical, user-friendly displays. A second report, the "Annual Detroit HIV Surveillance Report - Tables," contains data most commonly requested by agencies and individuals. Due to differences in the underlying dataset, do not compare any numbers or figures to old surveillance reports. For more on the difference see the "Annual Detroit HIV Surveillance Report - Tables."

Key Definitions

New Diagnoses: The number of cases newly diagnosed over a given period of time, usually a year. In HIV surveillance new diagnoses do not necessarily represent new infections as newly diagnosed cases may have been infected for many years.

Prevalence: The total number of persons currently living with HIV (PLWH).

Linked to Care: The proportion of newly diagnosed PLWH who have visited a doctor at least eight days after diagnosis (assessed by CD4, viral load, or genotype test).

In Care: The proportion of PLWH who visit a doctor at least once a year (assessed by CD4, viral load, or genotype test).

Community Viral Suppression: The proportion virally suppressed (≤200c/mL) out of all PLWH - higher levels of community viral suppression reduce HIV transmission.

Viral Suppression Rate: The proportion virally suppressed (≤200c/mL) out of PLWH in care.

HIV Over Time in Detroit City
New diagnoses and deaths have leveled off. In general, prevalence continues to rise.

2015 Prevalence 4,839 (dip due to emigration)

New Diagnoses & immigration

Prevalence

Deaths & emigration
The HIV epidemic represented as 100 people. The majority of persons living with HIV (PLWH) are black men and/or gay & bisexual men. Of women living with HIV, the vast majority are black.
In the City of Detroit, PLWH in care are very likely to be virally suppressed, improving the individual's prognosis and reducing transmission. However, **25% of PLWH in the City are not in care** (aka unmet need).

Unmet need is not equally distributed among PLWH. In Detroit, zip code 48226 experiences high unmet need. Other zip codes with high unmet need are distributed around the city.

Additionally in Detroit, teens, White & Latina/Hispanic females, persons who inject drugs and foreign born persons consistently have higher rates of unmet need.

**TEENS**

- 40% of persons **13-19 yrs old** are not in care.

**35% of persons WHO INJECT DRUGS** are not in care.

**38% of WHITE & LATINA/ HISPANIC females** are not in care.

**54% of FOREIGN BORN persons** are not in care.
Virally suppressed PLWH have improved prognoses and reduced transmission risk. In recent years, viral suppression rates and the community viral suppression levels continue to rise. However, the proportion of PLWH in care is stagnant. Community viral suppression levels can never surpass the proportion in care (as one cannot achieve viral suppression without first being in care).

Given these trends, one of two outcomes will likely be observed in the near future:
- Community viral suppression will stagnate, or
- If agencies and programs focus on retaining PLWH in care, it is likely community viral suppression will follow as viral suppression rates continue to rise.

In order for community viral suppression to continue increasing, the proportion of PLWH in care must increase.

Community viral suppression continues to rise in all age groups. However, younger persons still achieve viral suppression less often (have higher viral loads) than their older peers.
The epidemic continues to disproportionately affect the City of Detroit. The City had a diagnosis rate of 35 new cases per 100,000 residents.

Males 20-29 years old carry the heaviest burden of new diagnoses. Black males of every age experience disproportionately high rates of diagnosis.

*Does not include persons diagnosed in prison.
New Diagnoses - Linkage to Care
During 2015

Being linked to care quickly improves prognosis and decreases transmission. It is extremely important for the health of the individual and the prevention of HIV to link newly diagnosed persons to a health care provider as soon as possible.

White males are linked to care more quickly than black and Latino persons. White and Latina females not shone due to small numbers.

Linked →  ■ in 1 month  □ in 1-3 months

New Diagnoses - Linkage to Care
2006 - 2015

The proportion of persons who are linking up with a care provider continues to grow, however the proportion linked in 1 month has stagnated.
