STUDY OF
1950 TRAFFIC PAINT OPERATIONS

Part of a General Investigation of
Reflectorized Pavement Marking Paints
Devoted to the improvement of materials
and application methods.

Highway Research Project 47 G-36

Research Laboratory
Testing and Research Division
Report No. 158
March 15, 1951
STUDY OF
1950 TRAFFIC PAINT OPERATIONS

This is a report concerning an investigation of traffic marking paint operations for the 1950 season. The study was made at the request of Commissioner Charles M. Ziegler at a meeting held January 20, 1950, with respect to the Department's 1950 pavement marking program. It was agreed at that meeting that the research program should include the following objectives.

1. Hold a school for the paint crew personnel and roving superintendents to be handled jointly by the Maintenance, Planning and Traffic, and Testing and Research Divisions.

2. Keep daily records of the operations of each paint rig, including number of hours and lengths of striping.

3. The assignment of a representative of the Testing and Research Division to follow actual field applications and study all factors affecting wearing qualities.

All objectives were successfully completed and will be reported on as presented above.

PAINT SCHOOL

The paint school was held at Department Maintenance Garage in Mount Pleasant May 2 through May 5, 1950. All phases of traffic paint operations, applicable to paints, beads, and application details were discussed before the group by personnel from the Testing and Research laboratories, Planning and Traffic and Maintenance Divisions. The paint crews were also instructed on what was expected in the matter of securing field information and recording data.

At this time special field kits were made available to the paint crew foremen, each containing a wind gage, a sling psychrometer,
3 thermometers, 1 bottle of distilled water, 1 magnifying glass, pencils, printed forms and clean cloths, and the men concerned were instructed in the use of these instruments.

It was understood that each paint crew foreman would assume the responsibility of seeing that all record forms, samples appended, would be filled out completely, including two recordings in the morning and two in the afternoon. In addition, samples of the stripes would be taken at these same times, when possible, by the foremen, by placing metal "tins" where these would be passed over by the spray guns and bead dispensers. The tins were furnished by the Research Laboratory.

It was also arranged that Mr. Tom Green of Testing and Research Division would act in the capacity of inspector and observer, and would visit each of the paint crews in rotation throughout the State, wherever they should be operating at the time. Mr. Green was equipped with duplicate apparatus, and with forms to be filled out personally.

Complete daily operational records are in the Maintenance Division files.

FIELD OBSERVATIONS

The arrangements agreed upon at the paint school worked out fairly well during the course of the painting season, in spite of the added burden placed on the men. In general, the persons who actually took down the data are to be complimented on doing a good job. Nearly a thousand determinations were made of air temperature, air movement, slab temperature and relative humidity, and over half a thousand determinations of air pressures and drying times for white, yellow and black paint.
Hundreds of actual field samples were received by the laboratory. Field data has been summarized in Table I for reference.

The importance of relative humidity on drying time of paint and operation conditions was for the first time clearly revealed by the study. Further, additional data were secured on the phenomenon of paint wetting of beads and its effect on wearing properties of the paint stripe.

Effect of Relative Humidity on Drying Time of Paint

Soon after field operations had started, the paint crews encountered abnormally long drying times. This caused considerable tracking in dense traffic areas. A special study of the situation revealed that the prevailing high relative humidity at the time of paint application was causing the trouble.

Figure 1 shows the daily variation in relative humidity values for the State of Michigan over a five-year period for the months of June through August. From the curves in Figure 1, it may be observed that, at the time paint crews would ordinarily start operating in the morning, 7:30 A.M., the relative humidity would be in the neighborhood of 70 to 90 percent, then dropping to 40 to 60 percent around noon, gradually increasing in the afternoon. The inference from these data would be that painting operations should not start before 8:30 or 9:00 in the morning.

In view of this situation, instructions relative to painting, Supplement No. 3, were issued on June 20, 1950, to the effect that:

"If the relative humidity is not more than 65 percent, and is falling it shall be considered satisfactory to paint. If, however, the relative humidity is more than 60 percent, and is rising, painting shall be deferred until the humidity drops below 65 percent and continues to fall."

The data from field reports show a pronounced and definite relationship between drying time and relative humidity for both white and yellow paints. No such relationship was noted in the case of black paint products. See Figure 2. It is indicated from the curves in Figure 2 that in case of white and yellow paints, drying times from 20 to 60 minutes may be expected as normal. However, wind velocity, air, and pavement temperature will have considerable influence in lowering this figure in many instances.

Durability in Relation to Climatic Conditions

Until such time as further condition surveys have been made, little can be said about the effect of climatic conditions during painting upon the durability of the paint stripes.

There is, however, some early evidence that relative humidity at the time and site of application is without effect on the durability of standard
RELATIONSHIP BETWEEN DRYING TIME OF MSHD PAVEMENT MARKING PAINT AND RELATIVE HUMIDITY AT TIME AND SITE OF APPLICATION 1950 PAINTING SEASON

FIGURE 2
traffic marking stripes applied this year. See Figures 3 and 4. Further surveys will be required to substantiate or disprove this.

**Wetting of Beads by Paint in Relation to Stripe Durability**

It has been recognized that the surface attraction between paint and bead, which results in the wetting or non-wetting of the bead by the paint, must have considerable bearing on the length of time the bead remains embedded in the paint under constant bombardment by traffic and the elements and thus a pronounced effect on ultimate life of the paint stripe. Paints exhibiting a high tendency to climb up the sides of the beads and form deep, high-walled craters should be expected to retain the beads longer than paints which do not wet the beads as extensively or which may even repel the glass surfaces.

An attempt was made to follow the wetting of the beads by 1950 traffic paint and to compare this with other paint-bead combinations whose wetting properties have been recorded.

Reference to Figures 5 through 12 shows the excellent wetting of 1950 beads by 1950 white and yellow paints as compared with very poor wetting in the case of 1949 beads and paint.

SPECIAL TEST AREAS

During the course of the 1950 painting program, special traffic stripe test areas were established on M-43 between Lansing and East Lansing, on M-43 and US-16 in East Lansing, on US-16 west of Lansing City Limits, on US-27 at North City Limits of Lansing, and on US-16 between Fowlerville and New Hudson. In these test areas, paints and beads from various manufacturers were applied to determine the wearing qualities and bead retention properties of these traffic paints as compared to the Department's specification materials.

Personnel of the Testing and Research Division have made periodic inspections of these test installations and the results of their findings will be presented shortly in a separate report as a part of the Research Laboratory's general investigation on traffic marking paints.
SUMMARY

I. The following changes were made in 1950 operating conditions which were bound to give better traffic stripe performance in 1950 as compared to 1949.

1. The efficiency of the paint crews was materially increased by the paint school. Not only was the knowledge of the men increased on the subject of traffic paints, beads, and their application, but they were imbued with the desire to do a better job because of the interest being shown by the Administration.

2. The influence of humidity on drying time of the paint was determined and consequently immediate steps were taken to conform painting operations with humidity conditions to decrease drying time and insure minimum of tracking. Instructions were issued accordingly to all paint crews.

3. Better wetting of the beads by both 1950 white and yellow paints was obtained through modification of 1949 paint formulas.

4. The modifications in 1949 paint formulas were also directed toward producing a longer life product for 1950.

5. Better police control was experienced in 1950. More State Police were made available to control traffic. They were also more severe on persons crossing fresh traffic stripes. Scheduling of paint operations was better than in the past.

6. A greater educational program was put into effect by the Department through news release and radio warning motorists not to cross freshly painted traffic stripes.

II. As a result of the continuous field study during the 1950 painting program, additional changes have been made in 1950 paint and bead specifications which should produce even better wearing qualities for 1951. They are:

1. The diameter of the beads has been reduced to insure better penetration into the paint film and thus produce better bond and consequently impart longer wearing qualities to the stripe.

2. The white paint formula has been modified to produce a harder paint film, thus improving its wearing properties.
III. It is possible to realize even better paint wearing qualities through the following improvements:

1. Use of a paint stripe with small beads premixed in the paint and a quantity of large beads applied on top of the paint film.

2. By continuing studies to improve paint formulas, beads, and application methods.

CONCLUSION

Through the concerted efforts of those involved in the 1950 paint program there has resulted a definite improvement in workmanship accompanied by a marked increase in production. Also the wearing qualities and bead retention properties of the 1950 traffic paints have been found to be considerably better than those used in previous years.

INSTRUCTIONS FOR TAKING PAVEMENT MARKING DATA
SUPPLEMENT NO. 1

Under item "REMARKS", include the exact number of hours the paint striping machine worked and the exact length in miles of each color and type of striping done during the day.
INSTRUCTIONS FOR TAKING PAVEMENT MARKING DATA

SUPPLEMENT NO. 2

1. Revision to Supplement No. 1 (5-8-50).

Change the wording "and the exact length in miles of each color and type of striping done during day" to read - "and the total miles of each type of stripe laid during the day".

In other words, disregard the break-down of miles completed each day by color. This information is what you normally record on your daily report sheet.

2. Reports received to date indicate a very cooperative spirit from the paint crews and the data submitted so far is very complete. However, we would like at this time, to stress care in recording data. For example, we note such irregularities as failure to record both air pressures; reversing the recordings of wet and dry bulb readings; also not recording data in proper place on forms. Such things will no doubt disappear as the work progresses.

General information about the work being supplied under "REMARKS" is quite satisfactory and of great value.
Notice is hereby given to all paint spray crews that, effective immediately, the relative humidity of the air will be considered as a factor in determining whether or not to paint.

If the relative humidity is not more than 65 percent, and is falling, it shall be considered satisfactory to paint. If, however, the relative humidity is more than 60 percent, and is rising, painting shall be deferred until the humidity drops below 65 percent and continues to fall.

The data forwarded to the Laboratory have made possible a correlation of drying time with relative humidity which makes this step appear advisable at this time. It is hoped that by following this procedure, a considerable amount of trouble with traffic pick-up will be eliminated.

INSTRUCTIONS RELATIVE TO PAINTING
SUPPLEMENT NO. 4

Notice is hereby given to all paint spray crews that, effective immediately, painting shall not be started prior to 8:30 a.m. Painting shall be continued for a regular working day thereafter.

This supplement does not replace previous instructions but is in addition to them. All provisions of previous supplements are still in effect.
