Report No. 53
June 2, 1944
TO: W. W. McLaughlin

SUBJECT: Report on Para-Plastic Joint Seal Material
Expansion Joint Seal Study 36-G-4

In June, 1942, the Department purchased from the Servicized Products Corporation of Chicago, 170 lbs. of Para-Plastic joint-sealing compound for experimental purposes. This material was installed on the Michigan Test Road in all expansion joints in Series 9-A, station 162+10 to 181+00 inclusive. A usual survey of this installation was made on May 11, 1944. Another joint seal material called "Asphaltic Oil-Vultex" which was developed by the Department in 1939 was observed at the same time for comparative purposes. The results of the survey are as follows:

After two years of service the para-plastic material appeared live, plastic, and displayed considerable cohesion as illustrated in Figure 1 and 2. However, its bonding characteristics with the concrete were unusually poor and dirt penetrated into the joint as illustrated in Figures 3 and 4. Why such a condition developed is difficult to state. Although the pavement was 2 years old at the time of application of the Para-Plastic compound, the joints were free of bituminous material since a premolded rubber joint seal was used previously. Also the joints were carefully cleaned and dried before the material was installed. The compound showed a tendency to adhere to the joint filler underneath.

The Asphaltic Oil-Vultex was installed in series 4-6-7-8 and parts B1 and B2 of Series 10 during construction of Michigan Test Road. After 4 years in service the Asphaltic Oil-Vultex material was found to be extremely live and adhered perfectly to the concrete throughout the entire length of the joints as illustrated in Figures 5 and 6. This material has received no subsequent maintenance of any kind since installation.

A more complete and detailed survey is planned for this summer, which will cover all types of joint seals included for study on the Test Road Project.

Assistant Testing and Research Engineer in charge of Research
1. 36 G-4(G) Michigan Test Road. Paraplastic joint seal. 5-11-44. Station 166+10. View showing plasticity of material which was installed summer 1942. Material in itself is in a fair state of preservation. Material has high degree of cohesion.

2. 36 G-4(G) Michigan Test Road. Paraplastic joint seal. 5-11-44. Station 166+10. Note lack of bond between cement and material. Note unusual tendency for material to curl away from the cement allowing sand and dirt to enter joint. There is a certain amount of adhesion between joint sealer and joint filler underneath.
3. 36 G-4(G) Michigan Test Road. 5-11-44. Station 167+10. General view of joint with para-plastic joint seal. E.A.F.

4. 36 G-4(G) Michigan Test Road. 5-11-44. Station 168+10. Typical view of para-plastic joint seal under best conditions. Note lack of bond between material and cement.
5. 36 G-4(G) Michigan Test Road. 5-11-44. Station 169+10. View showing condition of joint underneath the seal. Note sealing material is live and resilient but lack bonding properties.

6. 36 G-4(G) Michigan Test Road. Thermoplastic seal. 5-11-44. Station 185+50. General view of thermoplastic seal material after 4 years. 100% perfect bond. No subsequent maintenance after installation. Material had considerable plasticity.
7. 36 G-4(G) Michigan Test Road. Oil-Vultex Seal 5-11-44, Station 199+90. After 4 years material is in excellent condition, 100% bonding, very plastic and adheres somewhat to finger upon penetration. No subsequent maintenance after installation.

8. 36 G-4(G) Michigan Test Road. 5-11-44, Station 199+90. General view of oil-vultex joint seal installation.
